Study of Fabric Waste Generated in the Woven Garments Industries in Bangladesh

Prof. Dr. Md. Mahbubul Haque, Md. Sakhawat Hossain Rizvi, Md. Mominur Rahman, Tanvir Ahmed Chowdhury, Mohammad Abdul Baset, Zobair Ahmad Noman

Abstract— The work reported in this paper is the study of waste generated in various stages of making five different types of woven garments. The three types of wastes that considered were e.g. i. waste of fabric, which were just left unused after completion of the order and is useable for making new apparels, ii. Net waste of fabrics which cannot be used at all may be regarded as hard waste and iii. Waste of completed garments. The study was conducted in five different garments industries. All the factories are located around Dhaka city. The products that were studied were Long Pant, Long Shirt, Short Cargo, Girl's Tops and Blouse. Information regarding above mentioned waste were collected using a data sheet and then analyzed to get three types of wastes of the five different factories separately. The wastes were then expressed as percentages of total quantity of fabric involved in that particular order. It was observed that on average 3.59% fabric remains unused, 1.99% completed apparel was wasted and hard waste was 2.15%. The wastes were found to vary to some extent among factories as well as among garments products. An important aspect about the wastes was that the unused fabric and completed garments wastes are sold in the local market at a very nominal price. The hard waste is the actual waste that is matter even then these wastes are sold to local people who converts these wastes into some other products like handicrafts, table mats etc. The wastes of usable fabric and completed garments are posing a threat to the competitiveness of local weaving industries. Development of an online database is proposed to monitor the imported woven fabrics.

Index Terms: Woven garments, Fabric waste, leftover fabric, left over garments, net waste, denim and non denim.

1 INTRODUCTION

Bangladesh is one of the leading exporters of readymade garments (RMG) products in the world. Export oriented RMG products can mainly be divided into two sub sectors namely a) Woven garments b) Knit Garments. For knit RMG export, 100% raw materials i.e. yarn and knit fabrics are being produced locally. However, in majority of the cases, the woven garments factory depends largely on the imported fabrics. As a result, a large amount of foreign currency goes to the fabric supplying countries.

industry leaves lot of wastage in form of fabric form whereas garments waste is not a large waste stream by weight or volume but has significant environmental impact connected to garments production [2]. F. Tabassum [3] found that every parts of garments wastes are valuable, recyclable and reusable where 70-80% are sold as jhuta. Textile Today[4], a leading textile magazine of Bangladesh published an article on 'Jhuta' (Waste) processing of Bangladesh's clothing industry, and mentioned that everyday approximately 550 tones garments wastes are exported which are mainly generated from fabric cutting in the garments industries. Elena Tomovska [5] mentioned that due to lack of workforce, technology, market and considering cost the management shows negligence about apparel waste. Nick [6] found that only 10.5 million tones clothing ends in landfills per year which is 6% of total garbage in New York. Parellax Limited [7], a medium size woven factory in China, studied on how to stop waste in their garment factory, they found that the amount of their waste is almost HK $ 1,480, 000 in a year. Mayedul Islam [8] mentioned that 10-15 % unavailable wastage occurs during cutting and marker making though in marker for larger pattern pieces marker efficiency and fabric consumption increases but for extreme large sizes (3XL) marker efficiency decreases but fabric consumption increases [9]. A study on clothing waste [10] reported that standard wastage percentages are 10-15%, 3-5% and 1-3% in the cutting, rejection and special operations respectively in knit apparel industries. Kasemset [11] showed that cutting waste

counts for as high as 16.36% of total material where 6.37% of waste was leftover from sewing and 0.09% from quality control. Another study found that waste from production lies between 10% to 30% of the intake materials, and that leftover percentage not less than 10% [12]. The two main authors [13] of the present papers found in a previous study on waste % in knit garments industry that on average more than 26.50 % waste is generated at various stages of which 13.57 % in the cutting section, 6.91% is in panel checking, 4.31% is in sewing section and 1.72% in the finishing section.

The present study has been conducted in woven garments to see exactly how much waste is generated at various stages of processing. The studies were conducted in five woven garments industries and information were collected for five different woven garments products. After careful observation of all wastes; three type of wastes were categorized e.g. (i) leftover waste as fabric, these were actually original but unused fabric, (ii) leftover waste as completed garment pieces, and (iii) Net waste or scrape -these are cut pieces of various sizes and shapes generated in the cutting table. Figure-1(a) -1 (e) shows wastes; how they look like?

Figure 1(a) Leftover waste as fabric roll

Figure 1(b) Leftover waste as yardage waste

2. MATERIALS AND METHODS

2.1 Factories and product selection and data collection

As was mentioned, five different garment industries were selected from greater Dhaka. The factories have been producing various types of woven garments products, among them five different types of woven products were selected e.g. 1) Long Pant, 2) Long Shirt, 3) Short Cargo, 4) Girl's Tops, 5) Blouse. Primary information obtained from the five factories were given below in tables 1-5.

2.2 Data analysis

Information shown in all the five tables were further studied and analyzed and three type of wastes were identified e.g. (i) Leftover waste as fabric, these were actually original but unused fabric, (ii) Leftover waste as garment pieces, and (iii) Net waste or scrape -these are cut pieces of various sizes and shapes generated in the cutting table. Figure-1 shows scrapes how they look like. Data about the three types of waste in the 5 different factories were extracted from tables 1-5 for five different items were summarized and shown in table 6. As was mentioned, the leftover waste was generated as fabric, completed garment pieces and scraps or net waste. Tables 7 shows the amount leftover fabric per day and table 8 shows the leftover fabric per year. The footnote shown below table 8 shows the details about how we got 295 days. Tables 9 shows the amount leftover garment per day and table 10 shows the leftover garments per year. The footnote shown below table 10 shows the details about how we got 295 days. Table 11 shows the net waste or scrap as percentage.

TABLE 06: PRODUCT WISE LEFTOVER WASTES (%) IN FIVE DIFFERENT FACTORIES

.

Item Name	Leftover Waste (%)	Factory 1	Factory 2	Factory 3	Factory 4	Factory 5	Average
Long Pant	Leftover (Fabric)	4.35	4.30	4.40	4.43	4.27	4.35
	Leftover (Pieces)	2.05	1.83	1.61	1.57	2.00	1.81
	Net Waste (Scrap)	2.63	2.53	2.83	2.81	2.72	2.70
Long Shirt	Leftover (Fabric)	3.22	3.32	3.42	3.38	3.45	3.36
	Leftover (Pieces)	1.22	1.65	2.01	1.60	2.44	1.78

Factory 5	16	23	10	36	29	23

TABLE 10: COMPLETED GARMENTS LEFTOVER IN THE FIVE DIFFERENT FACTORIES IN A YEAR.

Factory	Long Pant	Long Shirt	Short Cargo	Girl's Tops	Blouse	Average
Factory 1	4,130	2,655	2,655	7,375	5,015	4,425
Factory 2	4,130	4,130	2,655	7,080	6,785	5,015
Factory 3	4,425	5,605	3,835	5,900	7,670	5,605
Factory 4	3,245	3,540	2,360	5,605	8,260	4,720
Factory 5	4,720	6,785	2,950	10,620	8,555	6,785

** 295 Working days in a year (approximately). [Friday= 52; Government holiday= 8; Others holiday= 10]

TABLE 11: NET WASTE IN THE FIVE DIFFERENT FACTORIES AS PERCENTAGE.

Factory	Long Pant	Long Shirt	Short Cargo	Girl's Tops	Blouse	Average
Factory 1	2.63	2.22	2.74	1.63	1.64	2.17
Factory 2	2.53	2.20	2.59	1.54	1.40	2.05
Factory 3	2.83	2.23	2.57	1.46	1.54	2.13
Factory 4	2.81	2.36	2.71	1.69	1.56	2.23
Factory 5	2.72	2.33	2.72	1.59	1.59	2.19

3. RESULTS AND DISCUSSION

3.1 Leftover of Usable fabric

Table 6 shows the percentage of fabric leftover in the five different factories. It shows that for five different products the leftover of useable fabric varies between 2.97% and 4.43%. Table 7 shows the quantity of leftover fabric per day and it was multiplied by 295 (working day) to get the leftover fabric per year (shown in Table 8) in the five different factories. Therefore, there will be 3,29,815 yards of leftover fabric only in the five different factories in a year. The figures will be as high as 18,28,49,436 yds if the total number of factories are considered which are at present approximately 2772 units (source BGMEA). 100% leftover fabric is sold in the local market at a very nominal price for local consumption. It was reported that the leftover fabrics are sold in the local market at a very nominal price, which pose tremendous impact on the competency of the local fabric manufacturers. It is also widely believed that many industries imports much excess fabric than required and many importers imports fabric but in reality do not export anything just sell in the local market. It was also a matter of interest to see how the cost imported fabric can be so low? To study this it will be necessary to gather information from the supplying countries.

3.2 Leftover as garment pieces

It can be seen in table 6 that the leftover as garments pieces are between 1.22 and 3.05 percent. Like fabric, the leftover pieces per day and per year has been shown in table 9 and table 10. Like leftover fabric, the quantity of leftover garments per day average 18 and per year 5310 garments per factory and will be 14,719,320 pcs (for 2772 factories) are also huge if it is considered round the year. 100% leftover garments are also sold in the local market at a very nominal price.

3.3 Net waste

It can be seen in table 6 that the leftover as garments pieces is between 1.40 and 2.83 percent. These waste are also called hard waste and are sold in the local market for converting them to various types of usable products e.g. wearable shorts, tops for kids; recyclable yarn for fabric production, inner materials of mattress and cushion etc.

3.4 Impact of leftover useable fabric and completed garments

The leftover fabrics and garments shown in the tables 6-10 are estimation from five different factories, though the exact data varies among factories but probably the overall scenario are not very unrealistic. The data shown in various table were only leftover data but it is widely believed that many garments business owners import in the name of garments and then just sell the fabric in the local market. This aspect of unusual practice was not considered in the paper. The leftover fabrics and garments have changed the economy of the domestic weaving industries to a great extent. It may be mentioned that left fabric are good quality fabric and are consumed by the solvent consumers whose buying capacity is very good. Though they buy these at a nominal prices but it has great impact on the competitiveness of the domestic woven fabric manufacturers. This is because due to the fact that the woven fabric are sold in the domestic market at a very lower price than even manufacturing cost at the local weaving industries. It is also widely believed that lots of garments manufacturers import fabric in the name of garment and then sold in the local market. It may be mentioned that fabric is import for garment without any tax or vat. It was also learned that the fabric importers also enjoys advantages from supplier's side due to their own country's export policy under the umbrella of dual currency policy. Thus the import of woven fabric is to some extent relieving for the local consumers but a harsh suffocation for the local weaving industries. A suffocation that led to

breakdown of the backbone of the domestic (non denim) weaving sector of Bangladesh. Md. Masum [14], mentioned that the local suppliers can only meet 40% demands of woven fabric and 60% are imported. However in the recent years the scenario has been changed due to advancement of denim industries. It is a matter of interest that the locally produced denims are highly competitive as compared to the imported fabrics and local industries (both denim weaving and garmenting) have been doing excellent as compared competitor countries. It is also a matter of interest to study why the denim is so successful but non-denim weaving is not? It may be worth noting that the local consumption of denim is much lower in Bangladesh. Only certain young male populations are consuming denim trousers in a limited extent.

Due to import of large quantity of woven fabric for export market, huge amount of foreign currency goes to the fabric supplying countries. Apart from this the domestic demand of woven fabric is also very high though there is no exact data. However it seems that the local demand met by imported fabric is not less than that (woven fabric) are exported as completed garments. It seems that, in order to promote local weaving industries, the imported fabric must not be allowed to use in the domestic market. This means, the importers have to export everything they import. This is possible if they do it as stock lot or the importers sell their fabric to the smaller garments factories that can make and export as small lots. Though it will not be very easy to implement such policy but it seems that an online central server may be maintained. Whenever any fabric is imported it will be recorded in the server by the concerned users as well as Govt. agencies, and this type of data entry should be followed at every stage and finally the data about amount of excess fabric and completed garments may also be recorded. Though it will not be possible to prevent everything but it seems that if properly monitored then it will be possible to control to a great extent. Once if the domestic industries can stand in their own feet, the woven RMG export may reach new heights because import of the basic raw materials is always associated with some uncertainties.

4. CONCLUSION

Three types of waste e.g. leftover as fabric, leftover as garments and net waste were studied and reported. A very large amount of useable woven fabric and completed garments are generated as waste, however these waste fabric and garments are sold in the domestic market at a nominal price which affect the competiveness of the local weaving industries. In order to save the local weaving industries, the imported fabric and garments made from it should not be allowed to enter into the local market and these should be exported as stock lots. An online central server system can be introduced to monitor the excess fabric imported by the woven garments industries. Thus, it is only the net waste that is real waste, though in real sense that is not a waste either because these are again converted to other useable non-apparel, decorative or fancy products, but the impact of leftover fabrics and garments on the local industries needs to be studied and dealt with to safeguard the local weaving industries. Apart from this, if for any reasons like covid 19, supply chain is affected then the whole woven garments industries as well as the local consumers have to suffer severely due to hampering of import. Finally an important study may be carried out in the future to know why are local weaving factories cannot compete with imported fabric, though denim is competing very successfully.
