Fuzzy Markov Model for Web server Queues

(1) Dr. T. Chitrakala Rani, (2) R. Neelambari

Abstract:
In this paper queuing network model which can be used for web traffic networks has been studied. The model is an open network of infinite server queues where client arrive according to a non-homogenous fuzzy Poisson process. The interaction of the client with server is described by a Fuzzy Markov Renewal Process. The changing attribute of the customer in the customer are driven by continuous time Markov chain and therefore change as they move through the network. The transient and limited number of customers in disjoint sets of servers and attributes are investigated. These turns out to be independent fuzzy Poisson random variable. The covariance of number of clients in 2 sets of servers and attributes at different time epochs has also been discussed.

1 Introduction:
In this paper traffic model for a web multimedia wireless network has been considered. Characterized by interaction between client server network and fuzzy web traffic aspects. We suppose that there exists a finite set of servers. This choice avoids the detailed location description of client interaction with server in order to obtain an integrated manageable model. Since in real time the arrival rate of call vary significantly over time we consider that clients arrive according to a non homogeneous fuzzy Poisson process. The successive server visited by a client form a discrete time Markov chain and the server residence time have a general distribution which depends on the call being visited as well as both the previous server visited and the next server to be entered.

A new method have been introduced for finding fuzzy system reliability using fuzzy profust reliability theory[2]. In [5] the theoretical aspects of modeling the uncertainty associated with links are discussed, whereas in [1] unified fuzzy Markov model has been used in a communication network.

Web is being used by all short of people for different purpose.

A new method have been introduced for finding fuzzy system reliability using fuzzy profust reliability theory[2]. In [5] the theoretical aspects of modeling the uncertainty associated with links are discussed, whereas in [1] unified fuzzy Markov model has been used in a communication network.

Web is being used by all short of people for different purpose.

3 Preliminaries:
A fuzzy set is the generalization of the crisp sets. A fuzzy set can be defined mathematically by assigning to each possible individual in the universe of discourse a value representing its grade of membership in the fuzzy set. This grade corresponds to a degree to which that individual is similar or compatible with the concept represented by the fuzzy set.

Let $A$ be a fuzzy set, the membership function $\mu_A(x) \in [0, 1]$ is evaluated for $A$ at $x \in R$ where [0, 1] denotes the interval of real number from 0 to 1 including 0 and 1. Then the fuzzy sets are the subsets of real number system.

Let $\Gamma$ be the universe of discourse and $\psi$ be the power set of $\Gamma$. Then the possibility measure $\sigma$ is a mapping defined as follows [6]:
\[ \sigma : \psi \to [0, 1]\]

such that the following properties hold

i. \( \sigma(\emptyset) = 0 \) and \( \sigma(\Omega) = 1 \)

ii. \( \sigma(U_{A_j}) = \sup(\sigma(U_{A_j})) \)

for every arbitrary collection \( A_j \) of \( \psi \). The triplet \((\Omega, \psi, \sigma)\) is called as possibility space.

### 4 Fuzzy Markov model:

A fuzzy Markov model [6] is the model which has a finite number of states \( S_i \), \( i = 1, 2, 3, \ldots m \) at each transition \( n = 1, 2, 3, \ldots m \) together with fuzzy possibilities [2]

\[ \tilde{p}_{ij} = \sigma[X_{n+1} = S_i | X_n = S_j] \]

Let \( \mathcal{E} = \{1, 2, 3, \ldots m\} \) be the state space and \((\Gamma, \psi, \sigma)\) be a possibility space. Then

\[ X_n \]

represents the state and the nth transition and \( T_n \) represents the time of nth transition.

The process \((X_n, T_n)\), \( n \in \mathbb{N} \) is called non homogenous fuzzy Markov Renewal process if

\[ \sigma[X_n = j, T_n \leq t | X_{n-1} = \ldots = X_1 = i, T_{n-1} = \ldots \] \( \ldots = X_{n-1} = s] \]

Let \( \mathcal{E} = \{1, 2, 3, \ldots m\} \) be the state space and \((\Gamma, \psi, \sigma)\) be a possibility space. Then

\[ X_n \]

represents the state and the nth transition and \( T_n \) represents the time of nth transition.

The process \((X_n, T_n)\), \( n \in \mathbb{N} \) is called non- homogeneous fuzzy Markov Renewal process if

\[ \sigma[X_n = j, T_n \leq t | X_{n-1} = \ldots = X_1 = i, T_{n-1} = \ldots \] \( \ldots = X_{n-1} = s] \]

for all \( i \neq j \)

\[ \text{Transition distribution measure follows a homogenous fuzzy semi markov kernel [2].} \]

\[ \tilde{Q}_{ij} = \sigma[X_{n+1} = j, T_{n+1} \leq t | X_n = i] \]

\[ \tilde{r}_{ij}(t) = \lim_{n \to \infty} \tilde{Q}_{ij}(s, t), i, j \in \mathcal{E}, j \neq i \]

\[ \tilde{r}_{ij}(t) \]

represents the possibility of the client making his next transition to state \( j \) given that he entered state \( i \) at time \( t \). However before the entrance to \( j \) the process holds for a time \( s \) in state \( i \).

For \( i, j \in \mathcal{E} \). Define \( \tilde{G}_{ij}(t), t \geq 0 \) as the fuzzy distribution function of the time spent by the customer at the visiting node \( i \), given that its next visiting node is \( j \) [2].

\[ \tilde{G}_{ij}(t) = \begin{cases} \tilde{Q}_{ij}(t), & \text{if } \tilde{Q}_{ij}(t) \neq 0 \\ 1, & \text{if } \tilde{Q}_{ij}(t) = 0 \end{cases} \]

where

\[ \tilde{G}_{ij}(t) = \tilde{Q}_{ij}(t) = \sigma(T_{n+1} - T_n \leq t | X_{n+1} = j, X_n = i) \text{ if } \tilde{p}_{ij} > 0. \]

Let \( N^* = \inf \{n \geq 1; X_n, t > 0\} \) denotes the number of node transition made by an arbitrary customer before leaving the network.

\( T_N^* \)

denotes the time of departure so that \( X_N^* \) is the outside node reached by the customer at departure.

\( Y(t) \) denotes the location node of the \( l \)th customer at \( t \) unit of time after arriving the network.

\[ \{Y(t), t > 0\} \sim \{Y(t), t > 0\} \]

Where \( \{Y(t), t > 0\} \), being the minimal semi markov process associated to \( \{X_n, T_n\}, n \geq 0\) defined by

\[ Y(t) = \{X_n, T_n \leq t \leq T_n^* \text{ for all } t > 0 \text{ and } i, j \in \mathcal{E} \}

We have

\[ \tilde{p}_{ij}(t) = \sigma[Y(t) = j|Y(0) = i] = \min[\tilde{p}_{ij}(t), \tilde{r}_{ij}(t)] \]

### 4.2 Customers Attributes:

Suppose that each customer in the network has associated an attribute that many change with time. Let \( A(t) \) denotes the attributes of \( l \)th customers at \( t \) unit of time after arriving the network[7].

Suppose if

\[ \{A(t), t > 0\} \sim \{A(t), t > 0\} \]

with \( \{A(t), t > 0\} \) being a continuous time markov chain with finite state space \( S \).

For \( t > 0 \) and \( i, j \in \mathcal{E} \) we have

\[ \tilde{q}_{ij}(t) = P[A(t) = j] \]

\[ \tilde{q}_{ij}(t) = P[A(t) = j|A(0) = i] \]

Let us also suppose that the attribute of the customer and their locations in the network are independent (i.e)

\[ \{A(t), t \geq 0, 1 \leq 1 \} \perp \{Y(t), t > 0, 1 \geq 1 \} \]

### Transient Analysis

The arrival process of the customer to the network[7] Using time dependent coloring Poisson process we determine.

**Theorem 1:**

Suppose a customer enters to the network at time \( s \) is placed in cell \( k \) with probability \( \tilde{p}_k(s), k \in \mathcal{K} \) be finite and independent on other arrivals. For \( t \geq 0 \) and \( k \in \mathcal{K} \), let \( M_K(t), t \geq 0 \) denotes the number of customer placed in cell \( k \) unit time ‘t’. Then the point process \( \{M_K(t), t \geq 0\}, k \in \mathcal{K} \) are independent Non- homogenous fuzzy Poisson Process with intensity measure \( \mu_K(dt) = \tilde{p}_k(t), \lambda(t)dt, t \geq 0, k \in \mathcal{K} \) \( \text{for all } t \geq 0 \) the random variable \( \{M_K(t), k \in \mathcal{K}\} \) are independent and \( M_K(dt) = \text{Poisson}(\int_0^t \mu_K(ds)) \), \( k \in \mathcal{K} \)

**Note:**

Let us suppose \( \{s_i, 1 \geq 1\} \) denotes the sequence of arrival time to the network through input node \( i \) and let \( \{N_i(t), t \geq 0\} \) denotes the associated counting process.
Then by the theorem 1 with \( k = 1 \) and \( \tilde{P}_s(t) = \tilde{v}_i(t) \) we conclude that \( \{N_i(t), t \geq 0\} i \in I \) are independent non homogenous fuzzy Poisson process with intensity measure [4].

\[ \Lambda_i(dt) = \tilde{v}_i(t) \lambda_i(t) \, dt, \, i \in I \text{ and } t \geq 0. \]

Let \( B \subset I \times \mathbb{E} \). \( Y_{\beta}(t) \) denotes the number of customers whose pair of location node and attribute at time \( t \) belongs to the set \( B \). Then the number of customer that are in node \( j \) with attribute \( \beta \) at the time \( t \) and in the set \( \{B_{m}, m = 1, 2, 3, ..., M\} \) be a partition of the set \( M \times A \) then the fuzzy random variables then the random variable \( Y_{\beta_1}(t), Y_{\beta_2}(t), \ldots, Y_{\beta_m}(t) \) are independent and

\[ Y_{\beta_m}(t) \sim \text{Poisson} \left[ \sum_{t \in I} \sum_{i \in \mathbb{E}} \int_0^t \tilde{q}_{\beta}(t-s) \cdot \tilde{P}_{\beta}(t-s) \cdot \Lambda_i(ds) \right] \]

for \( 1 \leq m \leq M \) and \( t \geq 0 \)

Thus it has been shown that the number of customers whose pair of location node and attribute at time \( t \) belongs to each one of disjoint sets of pairs of a node and an attribute are independent fuzzy Poisson random variable.

**Covariance with respect to time:**

Here the covariance of the number of customers with given (single or multiple) pairs of location node and attribute at different times is determined.

**Theorem 3:**

For \( t, (t+h) \geq 0, j_1, j_2 \in M, \beta_1, \beta_2 \in A \)

\[ \text{Cov}(Y_{(j_1, \beta_1)}(t), Y_{(j_2, \beta_2)}(t+h)) = \sum_{i \in I} \int \tilde{q}_{\beta_1}(t-s) \tilde{q}_{\beta_2}(t-h) \cdot \tilde{P}_{\beta_1}(t-s) \cdot \tilde{P}_{\beta_2}(t-h) \cdot \Lambda_i(ds) \]

For \( t, (t+h) \geq 0, j_1, j_2 \in M, \beta_1, \beta_2 \in A \)

\[ X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h) \]

denotes number of customers that he is in the node \( j_1 \) with attribute \( \beta_1 \) at the time \( t \) and in the node \( j_2 \) with attribute \( \beta_2 \) at time \( t+h \). We conclude that \( X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h) \) is a fuzzy Poisson random variable with mean.

\[ E[X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h)] = \sum_{i \in I} \int \tilde{q}_{\beta_1}(t-s) \tilde{q}_{\beta_2}(t-h) \cdot \tilde{P}_{\beta_1}(t-s) \cdot \tilde{P}_{\beta_2}(t-h) \cdot \Lambda_i(ds) \]

If \( N_1, N_2, N_3 \) are independent fuzzy Poisson random variable then

\[ \text{Cov}(N_1 + N_2, N_1 + N_3) = E[N_1] \cdot \text{Cov}(Y_{(j_1, \beta_1)}(t), Y_{(j_2, \beta_2)}(t+h)) = E[X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h)] \]

\[ Y_{(j_1, \beta_1)}(t) = X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h) + Y_{(j_2, \beta_2)}(t) - X_{(j_1, \beta_1), (j_2, \beta_2)}(t, t+h) \]
\[ Y_{(j_1, \beta_1)}(t) = X_{(j_1, \beta_1)}(t, t + h) + Y_{(j_2, \beta_2)}(t, t + h) - X_{(j_2, \beta_2)}(t, t + h) \]

Hence the three random variables in the second member of last two equations are independent fuzzy Poisson random variable.

**ACKNOWLEDGMENT**

We wish to thank Dr. Dhanam, Associate Professor, Govt arts college, Pudukkotai for her guidance in many ways for shaping this paper.

**References:**

**Conclusion:**

The transient number of customer that have a given attributed and are located in a fixed node are shown to be independent Poisson random variable.
