Implementation of Parallel Interference Cancellation Algorithm for Rake Receiver and Comparison with MRC

Ms. Samta Jain

Abstract—In order to suppress the Multiple-Access Interference (MAI) in the DS CDMA system, a new RAKE receiver based on parallel interference elimination is proposed in this paper. The multiple-access interference is evaluated by tentative decision and known user information. Then the performance over Rayleigh fading channel are analyzed and compared to MRC receiver and PIC RAKE receiver. It is shown that RAKE receiver performance can be improved greatly by using Parallel Interference Cancellation (PIC) method with simple structure and easy implementation [1].

Index Terms—Parallel Interference Cancellation (PIC), RAKE receiver, Multiple-Access Interference (MAI), Maximum Ratio Combiner (MRC), Rayleigh fading.

I. INTRODUCTION

The CDMA system implemented by the direct-sequence spread spectrum (DS/SS) technique is the most promising multiplexing technology for cellular telecommunications services, such as personal communications, mobile telephony, and indoor wireless networks. The advantages of DS/SS for these services include superior operation in multipath environments, flexibility in the allocation of channels, the ability to operate asynchronously, privacy, and increased capacity in burst or fading channels [2]. One of the most attractive features of direct sequence code-division multiple access (DS-CDMA) systems is the capability of sharing bandwidth with narrowband communication systems without performance degradation of any one of the systems.

It is well known that the processing gain of a spread spectrum system will provide the system with a sufficient capability of interference rejection [3], [4], [5]. The higher the processing gain is, the better interference rejection the system has [5], [6]. For a moderate level of narrowband interference, the processing gain of the spread spectrum system often provides sufficient capability of interference rejection; hence, a simple despreading correlator can be employed to achieve a good performance. However, if the interfering signal is strong enough, the reliable communication becomes impossible even with the advantage of spectrum spreading. In these cases, the interference immunity can be improved significantly by using signal processing techniques which can complement the spread spectrum modulation.

According to the conventional DS-CDMA system analysis, we find out that the multiple access interference (MAI) is a major problem. Several methods have been proposed to suppress the interference in DS/SS transmission systems [6]. This paper concentrates on developing the parallel interference cancellation (PIC) to achieve a significant improvement in performance and increase the user capacity [7] and to reduce the effects of MAI and utilizes the processing gain with less noise enhancement.

The remainder of the paper is organized as follows. The system model is addressed in Section II. A system description is given in Section III. The DS-CDMA and proposed PIC with RAKE is described in this section. In Section IV, the simulation results and analysis for SNR vs BER is presented. Finally, the conclusions are given in Section V.

II. SYSTEM MODEL

A. Transmitter Model

Considering a single district with $K$ users, the baseband signal for the $K$th user is given by

$$s_k(t) = \sqrt{2E_k} d_k(t) c_k(t) \cos(\omega_t t + \theta_k)$$

(1)

Where $E_s$, $d_k(t)$ stand for the signal power and information stream for the $K$th user respectively, $\omega_k$ is the carrier frequency, $\theta_k$ is the carrier frequency phase, $c_k(t)$ is the signature wave for the $K$th user, $T$ is the chip width, $T_s$ is the every symbol width for user information stream. So the spread gain is obtained $N_s = T_s / T$.

A. Channel Model

Rake receivers are designed as taking out delay line model in frequency-selective channel, so the complex lowpass equivalent impulse response can be written as:

$$h(t) = \sum_{i=1}^{L} a_i e^{j\phi_i} \delta(t - iT_c)$$

(2)
In (2), \( L \) is resolvable path number, \( \alpha \) and \( \beta \) is the gain and phase of the \( i^{th} \) resolvable path respectively, \( \alpha \) and \( \beta \) obey to Rayleigh distribution in the Rayleigh channel.

B. The Receiving Signal

In this thesis, for simplicity, we consider a synchronous uplink CDMA system in the Rayleigh channel, the received signal can be written as:

\[
r(t) = \sum_{k=1}^{K} \sqrt{E_k} \sum_{j=1}^{L} \sum_{\ell=1}^{M} \alpha_{i_k} b_k(j) c_k(t) \cos(\beta_{i_k} + \theta_k) + n(t)
\]

(3)

In (3), \( n(t) \) represents the Additive White Gaussian Noise (AWGN) and its power spectrum density is \( \eta/2 \).

C. Rake parallel interference canceller

In the PIC with RAKE receiver, the RAKE fingers will separate the paths of rayleigh channel by proving the delay to the received signal. Thus, the output of the correlator can be written as:

\[
y_{k1}(i) = \int_{\tau}^{(i+1)\tau} r(t - i\tau) c_k(t) dt
\]

(4)

\[
N \sqrt{E_{ck}} \alpha_{i_k} b_k(i) + \sum_{k'=1}^{K} \sqrt{E_{ck'}} \sum_{l=1}^{L} \alpha_{i_{k'}} b_{k'}(i) \rho_{k',k} + n_k(i)
\]

(5)

Where:

\[
\rho_{k',k} = \int_0^\tau c_k(t) c_{k'}(t) dt
\]

(6)

In (6), the first item stands for signal; the second item is the multiple access interference (MAI) of the other (K-1) users to the \( K' \); the last is the additive white Gaussian noise (AWGN) and its average square error is \( N\eta/2 \).

III. SYSTEM DESCRIPTION

The comparison of RAKE-MRC with PIC-RAKE receiver is explained in this section as follows:

A. MRC with RAKE

The RAKE receiver was first introduced by Price and Green [8]. RAKE receivers take advantage of the energy present in multipath components by correlating with each path. The RAKE receiver is composed of several fingers which each resemble a single correlator. Each of these fingers has a different time delay and phase rotation associated with it that is matched to a multipath component. The crosscorrelation between a spread spectrum signal and a time-delayed version should be low; therefore the RAKE receiver will be able to develop an estimate based on only the multipath component. The resolution of the RAKE (i.e., the ability to resolve between separate multipaths) is dependent on the chip rate of the system. The multipath components must be separated by at least one chip period for the RAKE to resolve them.

The rake receiver consists of multiple correlators, in which the receive signal is multiplied by time-shifted versions of a locally generated code sequence. The intention is to separate signals such that each finger only sees signals coming in over a single (resolvable) path. The spreading code is chosen to have a very small autocorrelation value for any nonzero time offset. This avoids crosstalk between fingers.

Figure 1 shows the simulation model of RAKE finger. In RAKE receiver the received signal is delayed by one sample. In each finger the received signal is delayed by one sample. After delaying the received signal, the signal is multiplied by the PN sequence.

![Figure 1: Simulation Model of RAKE Fingers](http://www.ijser.org)

In MRC, all branches of the RAKE receiver are used simultaneously. The output of finger in each branch is chosen so that the output SNR is maximized. This is an analytical technique that works only if the individual signals must have the same phase shift before combining which would require estimation of channel parameters which can be difficult in a fast fading environment or a system that is non-coherent. The RAKE receiver using MRC maximizes the system’s instantaneous signal-to-noise ratio (SNR) when no narrowband interference exists. Its performance degrades in the presence of narrowband interference.

To traditional Rake receiver, the result using maximum ratio combining is:

\[
y_k(i) = \sum_{l=1}^{L} \alpha_{i_k} y_{k1}(i)
\]

(8)
Where $\alpha_{i,k}$ is the evaluation value for the $k^{th}$ user in the $l^{th}$ path.

Figure 2 shows the simulation model of MRC with RAKE receiver. The RAKE finger which has maximum SNR will be output of MRC.

![Figure 2: Simulation Model of MRC with RAKE Receiver](image)

**B. Parallel Interference Canceller (PIC) with RAKE Receiver**

According to the conventional DS-CDMA system analysis, we find out that the multiple access interference (MAI) is a major problem. However, we use the parallel interference cancellation (PIC) to achieve a significant improvement in performance and increase the user capacity [9].

The fig.3 shows the simulation model for PIC with RAKE receiver. RAKE fingers are used to separate the path of multi-path channel, since four paths channel is assumed, it is four fingers are used. After separation of the paths the signal is given to the PIC stages, where interference is cancelled out parallel.

![Figure 3: Simulation model for PIC with RAKE receiver](image)

After interference cancellation the signal is given to traditional Rake receiver, the result using maximum ratio combining is [10] as given in (8). When (8) is decided, the tentative test value about the symbol is obtained as:

$$\tilde{b}_k(i) = D(y_k(i)) \quad (9)$$

In (9), $D(.)$ stands for decision function, which may be hard decision or soft decision. Traditional PIC adopts hard decision. In this paper, we use simplified soft decision-linear decision.

**IV. SIMULATION RESULTS AND ANALYSIS**

**A. Simulation results for MRC with RAKE**

Figure 5 shows the results of MRC with RAKE on the basis of number of users. The parameters are chosen as: number of users $K$ is 2, 3 and 4, the value of spread factor $N_c$ is 32, the length of data bits sent is 1000 and the number of paths of Rayleigh Fading channel $l$ is 4.

![Figure 5: Performance of MRC with RAKE for Different Users](image)
Figure 6 show the result of MRC with RAKE on the basis of different spread factor. The number of users $K$ is 5.

B. Simulation Results for PIC with RAKE

Figure 7 shows the performance comparison of conventional PIC for different number of users. The parameters are chosen as: number of users $K$ is 1, 5 and 10, the value of spread factor $N_c$ is 32, the length of data bits sent is 1000 and the number of paths of Rayleigh Fading channel $l$ is 4.

Figure 7: Performance of PIC with RAKE for different Users

Figure 8 show the performance of PIC with RAKE for different Spread Factor. The number of users $K$ is 5.

C. Comparison Result of DS-CDMA and PIC with RAKE

Figure 9 show the results of comparison of MRC with RAKE and PIC with RAKE. The parameters are chosen as: number of users $K$ is 5, the value of spread factor $N_c$ is 64, the length of data bits sent is 1000 and the number of paths of Rayleigh Fading channel $l$ is 4.

In Figure 9, the parallel interference cancellation algorithm based on linear decision proposed in this paper is compared with MRC with RAKE. Each $L$ of them is 4. It can be seen from Fig.9 that when the signal-noise-ratio (SNR) is lower, the two kind receivers show little difference, but with the SNR increasing, the PIC with RAKE show superior performance than MRC with RAKE, especially, the PIC system proposed in this paper appears the best performance.

</table>

Table 1 and Table 2 are showing the performance of DS-CDMA and PIC with RAKE, respectively. The number of users chosen as 1, 5 and 10 and SNR is compared with bit error rate (BER). The values of SRN are taken as 0, 5 and 10 dB.

V. CONCLUSION

CDMA is a spread-spectrum multi-access technique which is currently the object of much attention. However, this technique suffers from severe reductions in system performance because of Multiple-Access Interference (MAI). In this paper, we have proposed and analyzed a MAI cancellation using PIC with RAKE for DS/CDMA signals over wireless channels that are characterized by multipath fading links. The proposed method, which is based on [1], is a parallel interference cancellation which attempts to cancel the MAI. Numerical results have demonstrated the effectiveness of the proposed method. Finally, it has been shown that the proposed cancellation strategy can alleviate the effects of the MAI and that significant system capacity improvement can be achieved using the proposed detector instead of the MRC with RAKE receiver.
