ABSTRACT: Metal oxide semiconductors are device used as a gas sensor to detect the gases in an environment. They are widely used for safety because, many harmful gases present in environment.TiO2 have better stability and remarkable properties as compared to other materials.TiO2 is used for anticorrosion, self-cleaning coating, paints to solar cells, and photo catalysts. The properties of thin film strongly depends on method of deposition and chosen conditions such as annealing temperature, film thickness, nature of crystalline, grain size, morphology, ion bombardment during deposition technique, impurity etc. The process of deposition of thin film such as CSD or CBD ,spin coating, dip coating chemical vapour deposition(CVD),plasma enhanced CVD ,Atomic layer deposition, successive ionic layer adsorption and reaction(SILAR),electro deposition, spray pyrolysis etc.

In this article we concentrated on spray pyrolysis technique which is the most promising method on large scale productivity. Spray pyrolysis is a chemical method which uses liquid precursor solution for film coating. TiO2 semiconductor metal oxide have been characterized using X-ray diffraction (XRD), Scanning electron microscopy (SEM),Transmission electron microscope (TEM),Atomic force microscopy etc. TiO2 thin films has better selectivity and sensitivity to act as a gas sensor.

Keywords: Titanium Dioxide thin films, Deposition technique, XRD, SEM etc.

1. Introduction

Today we are using different types of sensor devices for detecting physical, chemical and biological signals to be measured and recorded. Thin films of metal oxide semiconductors are widely used as many applications. In Recent technology lots of industries has developed their fabrication units with utilization of nanomaterials. There are many ways to fabricate thin films depending upon type of applications. Thin films deposited by wide range of varying their application with forms of chemical compositions [1].Titanium dioxide also called as titanium (IV) Oxide or Titania and naturally occurring oxide of titanium, its chemical formula is TiO2. Generally, it is sourced from ilmenite, rutile and anatase [2].

TiO2 powder is a fine, white powder provides a bright and white pigment. Titanium dioxide has been used in industry and consumer products including paints ,coating, adhesives ,paper, plastics and rubber, printing inks, coated fabrics and textiles as well as ceramics, floor covering roofing materials, cosmetics,toothpaste,soap,water treatments agent pharmaceuticals.
food colorants, automotive products, sunscreen, and catalysts [3]. TiO$_2$ is a transition metal oxide therefore remarkable optical and electronic properties in applications with solar cell, gas sensor and photo catalysts. Semiconductor metal oxide like TiO$_2$, SnO$_2$, ZnO etc. are present.

Titanium dioxide exists in many polymorphs. Among them Anatase, rutile, and Brookite and its Density 3.895, 4.2743 and 4.123[4]. These phases are characterized with high refractive index (anatase=2.488, rutile=2.609, brookite=2.583), low absorption and low dispersion [5].

2. Experimental

Spray Chemical Pyrolysis has been used to produce high purity, high performance and desired deposition on glass substrates to produce thin film of TiO$_2$. The pure TiO$_2$ thin films is successfully deposited by spraying 0.1M titanium trichloride solution on the glass substrate.

The electrical resistances, temperature coefficient of resistance and activation energy of the films has been calculated by measuring DC sheet resistance of the films at different temperatures with the help of static gas sensing system.

The XRD analysis of the prepared sample of TiO$_2$ thin film is done by using a BRUKER D8 ADVANCE diffractometer; Cu-K$_\alpha$ X-rays of wavelength($\lambda$)=1.5406Å and data taken by 2θ range of 20° to 80° and surface morphology was studied using scanning electron microscopy (SEM) with a JEOL-540LV microscope.

3. RESULTS AND DISCUSSION

3.1 X ray Diffractometer

![XRD Pattern of TiO$_2$ thin film](image-url)
Figure 1 shows the XRD spectra of the TiO$_2$ films, as deposited, after annealing at 400°C for 2hrs, the films are in anatase crystalline phase with a preferential orientation of (101), (210), (200) and (211) peaks also appeared. The peak confirms its anatase structure. The XRD pattern agrees with JCPDS card no.21-1272 (anatase TiO$_2$) [6].

The average particle size has been calculated by using the Debye-Scherer formula:

\[ D = \frac{K\lambda}{(\beta \cos \theta)} \]  \hspace{1cm} (1)

Where D is the mean size of crystallites (Particle Diameter in nm), K is crystallite shape factor a good approximation is 0.9, \( \lambda \) is the X-ray wavelength (0.1540nm), \( \beta \) is the full width at half the maximum (FWHM) in radians of the X-ray diffraction peak and \( \theta \) is the Braggs' angle (deg.).

\[ D = \frac{0.9 \lambda}{(\beta \cos \theta)} \]  \hspace{1cm} (2)

Bragg's Law refers to the simple equation:

\[ n\lambda = 2d \sin \theta \]  \hspace{1cm} (3)

Order of Reflection \( n \) \times \text{Wavelength} \( \lambda \) = 2 \times \text{Interplanar spacing} \( d \) \times \sin \theta

So, interplanar spacing can be calculated easily from the formula as:

\text{Interplanar spacing} \( d \) = \text{Order of Reflection} \( n \) \times \text{Wavelength} \( \lambda \) / 2 \times \sin \theta

Default value of wavelength \( \lambda \) of LASER is set to 0.15406nm, which is mostly used in the instruments and Order of Reflection \( n \) is 1, which is depends on how the width (0.94-scherical and 0.89-integral breadth of spherical crystals is round up 1) [7].

The instrumental broadening is generally done while determining average particle sizes which is less than 100nm. Instrumental broadening formula can be used only if strain and other sources of broadening are small.

The sample broadening is described by
\[ \text{FW(S)} \times \cos \theta = \frac{K + \lambda}{\text{Size}} + 4 \times \text{Strain} \times \sin \theta \]

The total broadening is described by

\[ \beta t^2 \approx \left( -\frac{D \cos \theta}{\lambda} \right) + \{4 \varepsilon \tan \theta \}^2 + \beta_0^2 \]

Fig. 2 Plot of the peak widths (FWHM) for TiO\textsubscript{2} thin film at various diffraction angle.

Using of a least squares fit, the particle size and strain can be calculated. Williamson-Hall gives the crystallite size and the strain. W-H plotted with \( \sin \theta \) on x and \( \beta \cos \theta \) on y axis (in radian) the slope of the fitted line gives you the crystallite size and the intercept gives you the strain.

Fig. 3. Williamson Hall Plot –TiO\textsubscript{2} thin film

Specific surface area describes the properties of the material, type and structure of the materials. SSA can be calculated using formula
\[ SSA = \frac{SA_d}{V_d \times \rho} \]  \hspace{1cm} (6)

\[ S = \frac{6 \times 10^3}{D \times \rho} \] \hspace{1cm} (7)

Where, SSA is Surface Area per mass, \( V_d \) is domain volume, \( SAd \) is surface area, \( D \) is the size of the particle and \( \rho \) is the density of the TiO\(_2\).

### 3.2. Scanning Electron Microscopy Analysis of TiO\(_2\) thin film

**Fig.4. SEM of TiO\(_2\) thin film sample at 400\(^0\)C**

A Scanning Electron Microscopy SEM [Model SPPU- JEOL 6300] is used for the study of microstructure as well as morphology of the thin film of TiO\(_2\). In this, film structure is like a web morphology. This images is recorded at X1000 and X3000 magnification [8].

### 3.3 Electrical Properties

#### 3.3.1 Resistance of the TiO\(_2\) thin film

The resistance of the film is measured using half bridge method with the help of static gas system. We observed that if temperature increases, resistance decreases due to increasing drift mobility of charge carriers and at certain level steady the resistance. Initially at Room temperatures it has no charge carriers and hence resistivity is high and at higher temperatures, a semi-conductor of valence electrons are free and is equal to conduction electrons that’s why resistivity decreases[10,11].
3.3.2. Activation Energy of the TiO2 thin Film

Arrhenius plot shows the log R versus reciprocal of temperature (1/T) plot TiO2 thin film. The temperature dependence of electrical conductivity(R) of TiO2 thin film follows the Arrhenius equation is given by

$$R = R_0 e^{-\Delta E/KT}$$  \hspace{1cm} (8)

Where $R_0$ is the resistance at room temperature, $\Delta E$ is the activation energy of the electrical conduction, $K$ is the Boltzmann constant and $T$ is the absolute temperature.

The activation energy has been determined by plotting graph between log R versus $1000/T$ (°K). It is found that the activation energy of TiO2 thin film is $1.60ev[12]$.

Fig.6. Variation of log R versus $1000/T$ for TiO2 thin film.

3.3.3. Temperature Coefficient of TiO2 Thin Film
With the help of activation energies, the temperature coefficient of resistivity (TCR) can be obtained and TCR is most important parameters for characterizing the detectivity of sensors, it is defined as,

\[
TCR = \frac{1}{R_0} \frac{\Delta R}{\Delta T}
\]………………………………………………………. (9)

Where, \(\Delta R = R_2 - R_1\), \(R_1\) in ohms at room temperature, \(R_2\) is resistance in ohms at operating temperature and \(\Delta T = T_2 - T_1\), \(T_1\) is the room temperature in °C and \(T_2\) is the operating temperature in °C.

The way to measure TCR is standardized in MIL-STD-202 Method 304. With this method, TCR is calculated for the range between -55°C and 25°C and between 25°C and 125°C. TCR depend on purity and temperature. TCR value of TiO\(_2\) thin film nearly goes to zero, TCR may be positive, negative or stable value [14].

![Fig.7. Activation Energy versus Temperature](image)

4. Sensitivity of LPG Gas with different Operating Temperature

Gas sensing will be depend on which material doped, thickness of film, deposition technique, annealing temperature. The detection principle of metal oxide sensors is based on change of the film resistance due to adsorption of the gas molecules on the surface of a semiconductor. Anatase phase having stable transition state, this phase is used in many application like solar cell, gas sensor due to its higher photocatalytic activity [15].

The most important parameters of gas sensor are Sensitivity, Selectivity and Stability, Detection limit, Dynamic range, Linearity, Resolution, Response time, Recovery time, working temperature and Hysteresis Life cycle. All are used to characterize the properties of a particular material or device. An ideal sensor would possess high sensitivity,
dynamic range, selectivity and stability, low detection limit, good linearity, small hysteresis and response time and long life cycle [16]. We find characteristics of sensitivity, Selectivity and Response time in static measurement system. The varying sensitivity with temperature by taking 1000ppm of LPG gas. Therefore 350°C is optimal temperature for LPG gas.

Sensitivity can be determined by equation [10]

\[ S = \frac{R_a - R_g}{R_a} \]  

\[ \text{........................................................................................................... (10)} \]

Where, Ra-Resistance of thin film in air atmosphere, Rg-Resistance of thin film in gaseous atmosphere.

CONCLUSION

We have successfully fabricated pure TiO2 thin film on glass substrate and studied structural, physical and electrical characterization. It was also found that the certain properties of gas sensing mechanisms for operating particular temperature.

ACKNOWLEDGEMENT

The authors are grateful to SPPU (Pune University) for valuable technical support for XRD, SEM analysis.
