

# Mathematical Approach to Image Steganography and Steganalysis

Kaustubh Choudhary

**Abstract**— Image based Steganography is the most preferred tool used by Terrorists and criminal organizations for securely broadcasting, dead-dropping and communicating information over the internet by hiding secret information in the images. Steganalysis is the technique of identifying such images which are although innocent in appearance but are still carrying any secret information. In this paper a mathematical model is designed for representing any such image based steganographic system. This mathematical model of any stego system can be used for determining vulnerabilities in the stego system as well as for steganalysing the stego images using same vulnerabilities. Based on these mathematical foundations three steganographic systems are evaluated for their strengths and vulnerabilities using MATLAB ©Image Processing Tool Box.

**Index Terms**— Cyber Crime, Image Steganography, LSB Insertion, Mathematical Model of Image Steganography

## 1 INTRODUCTION

Steganography is the art and science of writing hidden messages in such a way that no one, apart from the sender and intended recipient suspects the existence of the message. It is based on invisible communication and this technique strives to hide the very presence of the message itself from the observer. Herodotus's Histories describes the earliest type of steganography. It states that "The slave's head was shaved and then a Tattoo was inscribed on the scalp. When the slave's hair had grown back over the hidden tattoo, the slave was sent to the receiver. The recipient once again shaved the slave's head and retrieved the message".

All steganographic techniques use Cover-Object and the Stego-Object. Cover-object refers to the object used as the carrier to embed the messages into it. In the above example the slave's head (without tattoo) is the cover object. In modern context Images, file systems, audio, video, HTML pages, word documents and even email-spams can be used as cover objects. Stego-object is the one which is carrying the hidden message. I.e. in the above example the 'slaves head with fully grown hair and a hidden tattoo' is acting as the stego-object. Contemporary Steganography can be of various types depending upon the nature of the cover object and the method used for hiding information in that cover object. This technique is frequently used in espionage, organized crime and is especially popular among terrorist networks.

Among all those steganographic techniques the digital Image based steganography is most commonly used due to numerous advantages offered by it.[1] But the most important advantage is substantial difficulty in steganalysis of the digital image. Steganalysis is the process of identifying stego-objects from the bulk of innocent objects and further extracting the hidden information from the same. The identification of the steganographic signature in the innocent looking stego-image is the most difficult part

of any steganalysis algorithm. Once this malicious stego-image is identified then either the hidden data can be extracted from it or the data in it can be destroyed or can be even used for embedding counter-information in the same Digital image consists of numerous discrete pixels. Color of any pixel is depends upon the RGB Values of the pixel. For example in a 24 bit BMP image RGB values consists of three 8 bits for each R,G and B and thus a pixel is a combination of 256 different shades (ranging from intensity level of 0 to 255) of red, green and blue resulting in  $256 \times 256 \times 256$  or more than 16 million colors. Thus if the least significant bits in the R, G and B value are changed the pixel will have minimal degradation of  $2/256$  or 0.78125%. This minor degradation is psycho-visually imperceptible to us due to limitations in Human Visual System (HVS). But at the cost of this negligible degradation 3 bits (1 bits each from red, green and blue) are extracted out of every pixel for transmitting our secret information. The most of the Spatial Domain Image steganographic techniques use this method of LSB Insertion for hiding data in the image. There are other techniques also for hiding data in the image. For example Transformation Domain Steganography may use Discrete Cosine Transforms or Discrete Wavelet Transform for embedding data and some other steganographic algorithm may use a different color space itself (Example RGB may be converted to YCbCr and then various steganographic techniques can applied).

In this paper a Universal mathematical model is designed for representing any Image Based Steganographic System unambiguously as a mathematical structure. Based on this mathematical model three Spatial Domain Transformation based LSB Insertion algorithms are evaluated for susceptibility to steganalysis.

## 2 MATHEMATICAL MODEL OF IMAGE STEGANOGRAPHY SYSTEM

Any steganographic algorithm or simply Stego-algorithm is composed of Stego-Function  $F$  and inverse of Stego-Function  $F^{-1}$ .  $F$  takes Cover-Image  $C$  and Information  $I$  as input and generates Stego-Image  $S$  as the output. At the

He is young and dynamic scientist and has more than 5 Years of Experience in Teaching and Research. E-mail: choudhary.kaustubh@gmail.com

receiver end the Stego-Image S is fed to decoding algorithm which is mathematically inverse of Stego-Function F (represented as  $F^{-1}$ ) and produces Information I. These two function along with the entire set of their domain and co-domain form the Steganographic System  $\Psi$  (or simply Stego-system). Mathematically this can be represented as  $S = F(C, I)$  and  $I = F^{-1}(S)$  and  $\Psi = \{F, F^{-1}, C, S, I\}$ .

**2.1 UNIVERSAL STEGO SYSTEM: A PERFECT DEPICTER OF A STEGO-ALGORITHM**

A same stego-algorithm may operate on different cover images and may insert different informations in them. So any stego system  $\Psi = \{F, F^{-1}, C, S, I\}$  is different for every pair of cover image C and Information I even though the Algorithm of Stego- system  $\Psi$  given as  $\Psi(\text{Algorithm}) = \{F, F^{-1}\}$  remains the same for all those pairs. So we introduce the concept of Universal Stego System which is Universal Set of all stego systems  $\Psi = \{F, F^{-1}, C, S, I\}$  which have same Stego-Algorithm  $\Psi(\text{Algorithm}) = \{F, F^{-1}\}$ . We represent any Universal Stego System by  $\Phi = \{F, F^{-1}, \mathbb{C}, \mathbb{S}, \mathbb{I}\}$  where  $\mathbb{C}$  is set of all cover Images,  $\mathbb{S}$  is set of all stego-images and  $\mathbb{I}$  is set of all Information and stego algorithm of  $\Phi$  given as  $\Phi(\text{Algorithm}) = \{F, F^{-1}\}$ . Thus any stego system  $\Psi = \{F, F^{-1}, C, S, I\}$  is an instance of stego algorithm  $\{F, F^{-1}\}$  or Universal Stego System  $\Phi = \{F, F^{-1}, \mathbb{C}, \mathbb{S}, \mathbb{I}\}$ . Mathematically a Universal Stego System  $\Phi$  is:

$$\begin{aligned} \Phi &= \{F, F^{-1}, \mathbb{C}, \mathbb{S}, \mathbb{I}\} \\ &= \{x : x \text{ is stego-system } \Psi \text{ with } \Psi(\text{Algorithm}) = \{F, F^{-1}\}\} \\ \text{Stego-algorithm of } \Phi \text{ or } \Phi(\text{Algorithm}) &= \{F, F^{-1}\} \\ \mathbb{C} &= \{C : C \text{ is set of all Cover Images}\} \\ \mathbb{S} &= \{S : S \text{ is set of all Stego Images}\} \\ \mathbb{I} &= \{I : I \text{ is set of all Information}\} \\ \Psi &= \{C, S, I, F, F^{-1}\} \text{ and } \Psi \in \Phi \text{ iff } (C, I) \in \mathbb{C} \times \mathbb{I} \end{aligned} \tag{1}$$

**2.1.1 Security of Stego Algorithm**

Susceptibility to steganalysis of any stego algorithm depends upon its Security. As pointed by Cachin in his *Information theoretic model* [2] and Zollner et.al in *Modeling the security of steganographic systems* [3] the stego-algorithm  $\{F, F^{-1}\} \in \Phi$  is said to be  $\epsilon$ -secure ( $\epsilon \geq 0$ ) if the relative entropy (given by  $H(P_C || P_S)$ ) between the probability distributions (Probability Mass Function) of cover-image  $C \in \mathbb{C}$  and the stego-image  $S \in \mathbb{S}$  given as  $P_C$  and  $P_S$  respectively is at most  $\epsilon$  for every  $C, S$  and  $I$  in  $\Phi$ . The security of Stego Algorithm  $\{F, F^{-1}\} \in \Phi$  is same as security of Universal Stego System  $\Phi$  and are represented as  $\{F, F^{-1}\}(\alpha)$  or  $\Phi(\alpha)$  respectively. Therefore  $\{F, F^{-1}\}(\alpha)$  and  $\Phi(\alpha)$  are one and the same. By applying the concepts of Relative entropy as given in [2][3] it can be concluded that:

$$\begin{aligned} \text{If } \{F, F^{-1}\}(\alpha) \text{ or } \Phi(\alpha) = \epsilon \text{ then} \\ H(P_C || P_S) = \sum P_C \log_2 \frac{P_C}{P_S} \leq \epsilon \\ (\forall C \in \mathbb{C} \text{ and } \forall S \in \mathbb{S} \text{ where } C \in \Phi \text{ and } S \in \Phi) \\ (0 \log \frac{0}{0} = 0, p \log \frac{p}{0} = \infty \text{ and } p \log \frac{0}{p} = -\infty) \end{aligned} \tag{2}$$

The security of any Stego-System  $\Psi = \{F, F^{-1}, C, S, I\}$  is given as  $\Psi(\alpha)$  and is  $\epsilon$  secure (that is  $\Psi(\alpha) = \epsilon$ ) if  $H(P_C || P_S) = \epsilon$ . But this has very narrow connotation as Stego-Algorithm  $\{F, F^{-1}\}$  has to operate not just on  $C, S$  and  $I$  but on every  $C \in \mathbb{C}$ , every  $S \in \mathbb{S}$  and every  $I \in \mathbb{I}$ . But still the concept of security of any Stego-System  $\Psi = \{F, F^{-1}, C, S, I\}$  forms the basic building block of the concept of security of any Stego-Algorithm  $\{F, F^{-1}\}$  in Universal Stego System  $\Phi = \{F, F^{-1}, \mathbb{C}, \mathbb{S}, \mathbb{I}\}$ . This is because any stego algorithm  $\{F, F^{-1}\} \in \Phi$  is  $\epsilon$  secure (ie  $\{F, F^{-1}\}(\alpha)$  or  $\Phi(\alpha) = \epsilon$ ) then maximum value of security of any Stego-System  $\Psi \in \Phi$  (given as  $\Psi(\alpha)$ ) can be  $\epsilon$  for some  $\Psi \in \Phi$ . Mathematically this can be written as:

$$\{F, F^{-1}\}(\alpha) \text{ or } \Phi(\alpha) = \text{MAX} (\Psi_i(\alpha)) \quad \forall \Psi_i \in \Phi \tag{3}$$

Thus the security of Stego Algorithm  $\{F, F^{-1}\}$  or Universal Stego System  $\Phi$  is defined in terms of Stego System  $\Psi_i \in \Phi$ . According to Cachin a stego-system is perfectly secure if  $H(P_C || P_S) = 0$ , which is possible only when  $P_C = P_S$  and in such cases receiver is unable to distinguish between  $C$  and  $S$  as their probability distributions are same and this represents the Shannon's notion of perfect secrecy for cryptosystems[4]. However Chandramouli et.al in *Steganography Capacity: A Steganalysis Perspective* [4] have pointed that this definition of Security of stego-system is purely theoretical in nature because it assumes the Cover-object  $C$  to be perfectly random. But in reality the Image is not random and in some cases it is possible to steganalyse the image even if the probability distributions of the  $C$  and  $S$  are same. Hence in addition to parameter  $\epsilon$  some more parameters of security of any Universal stego system are devised.

**2.2 Preliminaries and Definition**

Using Cachin's Information theoretic model[3] and Chandramouli's Mathematical formulation of a Steganalytic Problem[6] and extending both to Image based stego-system a method is devised for representing this system mathematically. Based on this mathematical model a technique is devised for steganalysis of the stego image. Before we proceed to mathematical model of Image based stego-system we have to mathematically define the preliminary concepts to be used in this model.

**Definition 1 (Image)**

Every digital image is collection of discrete picture elements or pixels. Let  $M$  be any digital image with  $N$  pixels. So any particular pixel of image  $M$  is represented as  $M(z)$  and  $z$  can be any value from 1 to  $N$ . This  $M(z)$  can be a gray level intensity of the pixel in gray scale image or RGB or YCbCr value of the pixel in a color Image. Thus  $M(z)$  can be a set  $\{R(z), G(z), B(z)\}$  or equivalent gray scale representation or  $(R(z)+G(z)+B(z))/3$ . But it is always better to consider each  $R, G$  and  $B$  components individually because the averaging effect cause loss of vital steganographic information. Further  $\langle \{M\}, m \rangle$  is multiset of Image  $M$  such that  $M(z) \in \{M\}$  for every  $z = 1$  to  $N$  and  $m$

is a vector corresponding to the occurrence or count of every element  $M(z)$  in  $\{M\}$ . Mathematically an image  $M$  with  $N$  pixels is:

For any Image  $M$  with  $N$  pixels

$M(z)$  represents its pixels  $\forall z : 1 \leq z \leq N$

$M(z) = \{R(z), G(z), B(z)\}$  or  $(R(z)+G(z)+B(z))/3$

$\{M\} = \{M(z): z=1 \text{ to } N\}$

$m = \text{occurrence of any particular } M(z) \in \{M\}$

$\langle \{M\}, m \rangle$  is multiset representing image  $M$  (4)

**Definition 2 (Identical Images)**

Two images  $M$  and  $L$  with  $N$  pixels are said to be identical (represented as  $M \equiv L$ ) if they have pixel to pixel match. This means that two images are identical and absolutely same. Thus their difference image  $D = M - L$  will be a pure black image corresponding to zero matrix.

P	Q	R
S	Y	T
U	V	W

$M \equiv L \implies M(z) = N(z) \quad \forall z: 1 \leq z \leq N$  (5)

**Definition 3 (Probability distribution of Image)**

Probability distribution or Probability Mass Function represented as  $P(M)$  for image

$$M = \langle \{M\}, m \rangle$$

is a multiset  $\langle \{M\}, m' \rangle$  where

$$m' = \frac{m}{n(\langle \{M\}, m \rangle)}$$

and  $n(\langle \{M\}, m \rangle)$  is cardinality (number of elements) of multiset of the image  $M$  or simply total number of pixels in  $M$ .

For any Image  $M = \langle \{M\}, m \rangle$

$$P(M) = \langle \{M\}, m' \rangle$$

$$m' = \frac{m}{n(\langle \{M\}, m \rangle)} \quad (6)$$

**Definition 4 (Macro statistically Same Images)**

Two images  $M$  and  $L$  with  $N$  pixels are said to be Macro Statistically Same (represented as  $M \sim L$ ) if they have equal entropy, energy, contrast ratio, brightness and same histograms. However this does not mean that they are having pixel to pixel match and may not be identical. It simply means that the probability distributions of their pixels are equal. Thus if  $M \sim L$  then  $\langle \{M\}, m \rangle = \langle \{L\}, l \rangle$  or in terms of probability distribution  $P(M) = P(L)$ . In other words images  $M$  and  $L$  will have same number of occurrence of any certain pixel intensity but it is not necessary that pixels in the two images will match at every position i.e.  $M(z) \neq N(z)$  for any particular  $z$  from 1 to  $N$  in the two images. Thus

$$M \sim L \implies \langle \{M\}, m \rangle = \langle \{L\}, l \rangle \text{ or } P(M) = P(L).$$

Also  $M \sim L \not\Rightarrow M \equiv L$ . (7)

**Definition 5 (Neighborhood or Locality of Pixel)**

If  $\ell(M(z))$  is said to be set of neighboring pixels of any pixel  $M(z)$  in image  $M$ . Then any  $n_i \in \ell(M(z))$  will be such that  $d(n_i, M(z)) \leq \lambda$  where  $d$  is a function which calculates distance (can be Euclidean, City-Block, Chess Board or any other type depending upon the steganographic algorithm) between its inputs (ie  $n_i$  and  $M(z)$ ) and  $\lambda$  is measurement of degree of neighbourhood and should be minimum (Generally equal to 1 pixel) but also depends upon the steganographic algorithm used by stegosystem  $\Psi$ . Mathematically this can be represented as:

$$\ell(M(z)) = \{M(x): M(x) \in M \text{ and } d(M(x), M(z)) \leq \lambda\} \quad (8)$$

In Fig 1 an arbitrary pixel  $Y$  is shown with its neighbors  $P, Q, R, S, T, U, V$  and  $W$ . We represent this pixel  $Y$  as  $\dot{Y}$  in mathematical notation. Thus  $\ell(\dot{Y}) = \{P, Q, R, S, T, U, V, W\}$  is set of neighboring pixels of pixel  $Y$ . Here  $\lambda = 1$  and distance function  $d$  calculates Chess Board Distance.

Fig 1 Pixel Y

**Definition 6 (Adjacent Neighbors of Pixel)**

Set of Adjacent Neighbors of a pixel  $M(z)$  is given as  $\mathcal{A}(M(z))$ . Thus  $\mathcal{A}(M(z))$  is a collection of set  $\{M(x), M(y)\}$  such that  $M(x) \in \ell(M(z))$  and  $M(y) \in \ell(M(z))$  and they are adjacent i.e  $d(M(x), M(y)) = 1$  where  $d$  is a function which calculates distance. Mathematically:

$$\mathcal{A}(M(z)) = \{\{M(x), M(y)\}: M(x) \in \ell(M(z)) \text{ and } M(y) \in \ell(M(z)) \text{ and } d(M(x), M(y)) = 1\} \quad (9)$$

In Fig 1 for an arbitrary pixel  $Y$  with  $\ell(\dot{Y}) = \{P, Q, R, S, T, U, V, W\}$  the  $\mathcal{A}(\dot{Y}) = \{\{P, Q\}, \{Q, R\}, \{R, T\}, \{T, W\}, \{W, V\}, \{V, U\}, \{U, S\}, \{S, P\}\}$ .

**Definition 7 (Pixel Aberration)**

Pixel Aberration of any Pixel  $M(z)$  from its neighborhood  $\ell(M(z))$  in terms of Standard Deviation of  $\ell(M(z))$  is given as  $\delta(M(z), \ell(M(z)))$ . It is a quantifier which gives the idea of the amount of deviation of the pixel from its neighborhood. In any natural image a pixel  $M(z)$  is expected to be as much different from its neighborhood as the adjacent pixels in  $\ell(M(z))$  themselves are.

For any pixel  $M(z)$  the mean of its absolute difference from its neighborhood  $\ell(M(z))$  is given as  $\overline{(M(z), \ell(M(z)))}$ . And the set representing the absolute differences of the adjacent neighbors of  $M(z)$  among themselves is given as

$\mathcal{D}(\mathcal{A}(M(z)))$ . The mean of the values of  $\mathcal{D}(\mathcal{A}(M(z)))$  is given as  $\overline{D(A(M(z)))}$  and Standard Deviation of the values of  $\mathcal{D}(\mathcal{A}(M(z)))$  is given as  $\sigma(\mathcal{D}(\mathcal{A}(M(z))))$ . Since  $M(z)$  is also a immediate neighbor of  $\ell(M(z))$  so  $(M(z), \ell(M(z)))$  must be within the limits of standard deviation of  $\mathcal{D}(\mathcal{A}(M(z)))$  and mean of  $\mathcal{D}(\mathcal{A}(M(z)))$ . This degree of deviation of  $M(z)$  from its neighbors  $\ell(M(z))$  in terms of  $\sigma(\mathcal{D}(\mathcal{A}(M(z))))$  and  $\overline{D(A(M(z)))}$  is quantified as  $\delta(M(z), \ell(M(z)))$  and hence it represents the aberration in the pixel  $M(z)$ .

In terms of Fig 1 the mean of the differences of pixel Y with its neighbors i.e. elements of  $\ell(Y)$  is given as Y-P, Y-Q, Y-R, Y-S, Y-T, Y-U, Y-V and Y-W and should be close to the differences of the adjacent pixels in  $\ell(\dot{Y})$  i.e. difference of the elements of {P,Q}, {Q,R}, {R,T}, {T,W}, {W,V}, {V,U}, {U,S} and {S,P} or simply P-Q, Q-R, R-T, T-W, W-V, V-U, U-S and S-P. Thus  $(\dot{Y}, \ell(\dot{Y}))$  is mean of modulus of Y-P, Y-Q, Y-R, Y-S, Y-T, Y-U, Y-V and Y-W and  $\mathcal{D}(\mathcal{A}(\dot{Y})) = \{\text{modulus of P-Q, Q-R, R-T, T-W, W-V, V-U, U-S and S-P}\}$ . So aberration in pixel Y with respect to its neighborhood  $\ell(\dot{Y})$  given as  $\delta(\dot{Y}, \ell(\dot{Y}))$  should be within the limits of standard deviation of  $\mathcal{D}(\mathcal{A}(\dot{Y}))$  and its mean  $\overline{D(A(\dot{Y}))}$ .

Mathematically:

$$\overline{(M(z), \ell(M(z)))} = \frac{1}{n(\ell(M(z)))} \sum_{p \in \ell(M(z))} |p - M(z)|$$

$$\mathcal{D}(\mathcal{A}(M(z))) = \{|x - y| : (x, y) \in \mathcal{A}(M(z))\}$$

$$\delta(M(z), \ell(M(z))) = \frac{(\overline{(M(z), \ell(M(z)))} - \overline{D(\mathcal{A}(M(z)))})}{\sigma(\mathcal{D}(\mathcal{A}(M(z))))} \tag{10}$$

**Definition 8 (Pixel Aberration of Image)**

In any image M with N pixels the Pixel aberration of image M is given as  $\delta(M)$ . It is the weighted mean of the modulus of the pixel aberrations of the pixels of the entire image M. Since for any image M the  $\delta(M(z), \ell(M(z)))$  is the measure of deviation of  $M(z)$  from its neighborhood  $\ell(M(z))$  in terms of standard deviation so majority of pixels have this values located close to zero and approximately more than 68% of the pixels have pixel aberration within  $\pm 1$  ( as per 3 Sigma or 68-95-99.7 rule of Statistics). Hence the simple mean of  $\delta(M(z), \ell(m(z)))$  is very close to zero and is insignificantly small for all images. Since by pixel aberration analysis we have to identify those images which have larger pixel aberrations so as a remedy very small weights are assigned to less deviated values (majority of pixels which have low pixel aberration values) and larger weights are assigned to more deviated values (few counted pixels have large pixel aberrations). Thus value of  $\delta(M)$  for the Image M with N pixels is given in (11) as:

$$\delta(M) = \frac{\sum_{z=1}^N |\delta(M(z), \ell(M(z)))| \times W(z)}{\sum_{z=1}^N W(z)} \tag{11}$$

The weight  $W(z)$  for the pixel  $M(z)$  is much smaller for small values of  $\delta(M(z), \ell(m(z)))$  and quite large for big values of  $\delta(M(z), \ell(m(z)))$ . Thus  $W(z)$  is large for pixel having greater pixel aberration and very small for pixels having lesser pixel aberration. Such weights can be computed by taking cube of the value of pixel aberration in terms of the standard deviation. In other words the weight  $W(z)$  for any Pixel  $M(z)$  in image M is given as

$$W(z) = \left| \frac{\delta(M(z), \ell(M(z))) - \text{MEAN}_{z=1}^{z=N}(\delta(M(z), \ell(M(z))))}{\text{STD}_{z=1}^{z=N}(\delta(M(z), \ell(M(z))))} \right|^3$$

**(12)**

Although we may avoid taking weighted mean and we can use simple mean but for that we have to consider only those values of  $\delta(M(z), \ell(M(z)))$  for determining mean which are above or below certain threshold  $\pm \check{\tau}$  and rest of the values can be filtered. This value of  $\check{\tau}$  is generally given in terms of standard deviation of  $\delta(M(z), \ell(M(z)))$  from  $z = 1$  to  $N$  and is represented as  $\tau$ . Thus Mean Pixel Aberration of Image M at threshold  $\tau$  is represented as  $\delta(M, \tau)$  and mathematically defined as:

$$\check{\tau} = \text{MEAN}_{z=1}^{z=N}(\delta(M(z), \ell(M(z)))) \pm \tau \times \text{STD}_{z=1}^{z=N}(\delta(M(z), \ell(M(z))))$$

$$\tau = \frac{\check{\tau} - \text{MEAN}_{z=1}^{z=N}(\delta(M(z), \ell(M(z))))}{\text{STD}_{z=1}^{z=N}(\delta(M(z), \ell(M(z))))}$$

$$\delta(M, \tau) = \frac{1}{N} \sum_{\substack{|\delta(M(z), \ell(M(z)))| \geq \check{\tau} \\ M(z) \in S \quad \forall z: 1 \leq z \leq N}} |\delta(M(z), \ell(M(z)))| \tag{13}$$

Thus this value of  $\tau$  depends on smoothness of the cover image and the type of aberration we are interested in. In unsmooth cover images the differences of the pixels with their

neighbors is quite large (for example an image of a Forest or Valley) and hence the value of  $\delta(M, \tau)$  at larger  $\tau$  represents the mean of only those deviations which are larger than  $\tau$ . Whereas for smooth cover images like clear blue sky the aberration is already very low and hence smaller value of  $\tau$  produces good result.

**Definition 9 (Range of Pixel Aberration in the Image)**

In any image M with N pixels the Range of Pixel aberration of image M is given as  $\mathcal{R}(M)$ . It is the difference of the Maximum Pixel Aberration  $\mathcal{R}(M)^\uparrow$  in the image M and Minimum Pixel Aberration  $\mathcal{R}(M)_\downarrow$  in the Image M. Thus Mathematically

$$\begin{aligned} \mathcal{R}(M)^\uparrow &= \max_{1 \leq z \leq N} (\delta(M(z), \ell(M(z)))) \\ \mathcal{R}(M)_\downarrow &= \min_{1 \leq z \leq N} (\delta(M(z), \ell(M(z)))) \\ \mathcal{R}(M) &= \mathcal{R}(M)^\uparrow - \mathcal{R}(M)_\downarrow \end{aligned} \tag{14}$$

**Definition 10 (Maximum Deviation in the Pixel Aberration of the Image)**

In any image M with N pixels the Maximum Pixel Aberration in M given as  $\Delta(M)$  is the maximum pixel aberration in absolute terms in the image M.  $\tau$  corresponding to  $\delta(M(z), \ell(M(z))) = \Delta(M)$  is represented as  $\mathcal{J}$ . Thus

$$\Delta(M) = \text{MAX} ( | \mathcal{R}(M)^\uparrow |, | \mathcal{R}(M)_\downarrow | ) \tag{15}$$

$$\mathcal{J} = : \check{\tau} = \Delta(M)$$

$$\mathcal{J} = \frac{\Delta(M) - \text{MEAN}_{z=1}^z \delta(M(z), \ell(M(z)))}{\text{STD}_{z=1}^z \delta(M(z), \ell(M(z)))} \tag{16}$$

**2.3 DETAILED MATHEMATICAL MODEL OF ANY IMAGE BASED STEGO ALGORITHM**

In (3) it has been very clearly shown that security of any stego system  $\Psi = \{F, F^{-1}, C, S, I\}$  is the basic building block of security of the stego-algorithm  $\{F, F^{-1}\}$ . So for the sake of simplicity only stego-system is considered. Let  $\Psi = \{F, F^{-1}, C, S, I\}$  be any Image Steganographic System with  $F, F^{-1}, C, S$  and  $I$  having the same meaning as mentioned in previous section. Thus  $S = F(C, I)$  and  $I = F^{-1}(S)$  also holds well. Now let us assume that Cover Image C consists of N discrete pixels represented by  $C(1), C(2), \dots, C(N)$ . Although cover image C is meant for storing Information I. But any arbitrary pixel  $C(z)$  of C can at max store only a limited part of Information I. Let this small part of I stored in  $C(z)$  be represented as  $I(z)$ . Thus our Information I can be broken to K parts represented by  $I(1), I(2) \dots, I(K), K \leq N$  such that any

$I(z)$  is the information stored in any particular pixel  $C(z)$  for any  $z \leq N$ . If information I is smaller than the cover-image C i.e. if  $K < N$  then the remaining  $I(z)$  from  $z = K+1$  to  $N$  can be thought to be empty or Null set and given as  $I(z) = \{\}$  for  $z = K+1$  to  $N$ . Thus the cardinality of both I and C (given as  $n(I)$  and  $n(C)$  respectively) is made equal i.e.  $N$ . Since  $S = F(C, I)$  so corresponding to every  $C(z)$  in C we have a unique  $S(z)$  in S. Using the notations of Set Theory the same is mathematically explained in (17).

The stego-function  $F: (C, I) \rightarrow S$  can be redefined at pixel level as  $S(z) = \alpha(z) [C(z) \bullet I(z)]$  where  $\bullet$  is any operator used by stego-function F acting over C and I to produce S and  $\alpha(z) \geq 0$  is factor which strengthens  $\Psi$  for  $z = 1$  to  $N$ . Thus  $\alpha(z) \forall z: 1 \leq z \leq N$  is strengthening factor of stego system  $\Psi$  and helps it in achieving secure  $\Psi$  (ie  $\alpha(z)$  for  $z = 1$  to  $N$  is the factor which helps in achieving  $\Psi(\alpha)$ ).

The inverse stego function  $F^{-1}: (S) \rightarrow I$  can be redefined at pixel level as  $I(z) = \Theta(S(z))$  where  $\Theta$  is a unary operator used by  $F^{-1}$  acting on S to produce I and hence indirectly C also. Thus algorithmically unary operator  $\Theta$  is inverse of the operator  $\bullet$ .

$$\Psi = \{C, S, I, F, F^{-1}\}$$

$$n(\{C, c\}) = N \text{ and any pixel of } C \text{ is } C(z) \forall z: 1 \leq z \leq N$$

$$S = F(C, I)$$

$$I = F^{-1}(S)$$

$I(z)$  is Information stored in any particular Pixel  $C(z)$

$$\{C, c\} = \cup_{z=1}^N C(z) \text{ and } I = \cup_{z=1}^K I(z) \text{ where } K \leq N$$

In order to have  $n(\{C, c\}) = n(I) = N$  even if  $K < N$

we have to assume  $I(z) = \{\} \forall z: K+1 \leq z \leq N$

Thus after having cardinality of C and I equal we can say

$$\forall C(z) \in C \exists \text{ unique } I(z) \in I.$$

Also since  $S = F(C, I)$  so  $\forall C(z) \in C \exists \text{ unique } S(z) \in S.$

$$\text{Thus } \{S, s\} = \cup_{z=1}^N S(z)$$

$$\tag{17}$$

**2.3.1 Parameters for Measuring Strength of Stego Algorithm**

Strengthening Factor  $\alpha(z) \forall z: 1 \leq z \leq N$ , keeps  $S(z)$  such that it is least susceptible to any steganalysis attacks by making S perfectly resemble an Innocent Image i.e. without any distortions. Therefore this  $\alpha(z)$  has to meet four main requirements which are explained next.

**Requirement 1**

Using operator  $\bullet$  the  $\alpha(z)$  should map  $C(z)$  and  $I(z)$  to  $S(z)$  in such a way that relative entropy of cover and stego image given as  $H(P(C) || P(S))$  should be minimum possible. Here  $P(C)$  is probability distribution (Probability Mass Function) of C and  $P(S)$  is probability distribution of S and  $H(P(C) || P(S))$  is relative entropy of P(C) with P(S). This requirement is derived from (1) as mentioned in section 2.1.1. This simply means that macro statistical parameters of the Cover-Image C and Stego-Image S

should be almost same or in terms of relative entropy should be minimum possible. This requirement is extension of Cachin's Information theoretic model in terms of  $\alpha$ . Mathematically this can be expressed as

$\alpha(z)$  should be such that:

$$H(P(C)||P(S)) = \sum P(C) \log_2 \frac{P(C)}{P(S)} = \epsilon \tag{18}$$

Where  $P(C)$  and  $P(S)$  are probability distribution of  $C(z)$  and  $S(z) \forall z: 1 \leq z \leq N$  and such a stego-system is said to be  $\epsilon$  Secure.

In order to achieve this requirement the stego function  $F: (C, I) \rightarrow S$  will macro-statistically redistribute the pixels of  $C$  in such a way that even though corresponding pixels  $C(z)$  and  $S(z)$  may not be same but still probability distribution of pixels  $C(z)$  in  $C$  and  $S(z)$  in  $S$  for  $z = 1$  to  $N$  will remain same in other words  $C \sim S$  will be achieved. Thus by fulfilling this requirement (assuming  $\epsilon = 0$ ) the Cover Image and the Stego Image will have same Histogram, Brightness, entropy, energy, contrast ratio and all other macro statistical parameters even if  $C \neq S$  that is  $C(z) \neq S(z) \forall z: 1 \leq z \leq N$ .

**Requirement 2**

If only Requirement 1 is met we may have a situation where even though the cover-image may look macro-statistically same (in terms of Histogram, Brightness, entropy, energy, contrast ratio etc) as stego-image but still they may have significantly different pixel to pixel correspondence between  $C$  and  $S$ . I.e. any particular pixel  $S(z)$  of  $S$  may be considerably different from  $C(z)$  of  $C$  thus revealing the distortions in  $S(z)$  and hence making  $S$  susceptible to Steganalysis. Thus in addition to macro-statistical redistribution of the pixels of cover image (as mentioned in Requirement 1) the stego-algorithm must redistribute the pixels of the neighborhood of every pixel  $C(z)$  in  $C$  (i.e.  $\forall z: 1 \leq z \leq N$ ) is such way that two corresponding pixels  $C(z)$  and  $S(z)$  should have same probability distribution of their neighborhood. Thus  $\alpha(z)$  should meet another requirement:

Using operator  $\bullet$  the  $\alpha(z)$  should map  $C(z)$  and  $I(z)$  to  $S(z)$  in such a way that the relative entropy between the Neighborhood of  $C(z)$  and  $S(z)$  (or Local Relative Entropy) should be least possible  $\forall z: 1 \leq z \leq N$ . Thus any Image based Stego-System  $\Psi$  is said to be  $\xi$  Secure if the mean of the relative entropies of the neighborhood of  $C(z)$  and  $S(z)$  for all  $C(z)$  in  $C$  and  $S(z)$  in  $S$  (that is  $\forall z: 1 \leq z \leq N$ ) is  $\xi$ . Thus  $\alpha(z)$  should be such that  $\xi$  is minimum where  $\xi$  is given as

$$\begin{aligned} & \frac{1}{N} \sum_{z=1}^{z=N} H(P(\ell(C(z)))||P(\ell(S(z)))) \\ & = \frac{1}{N} \sum_{z=1}^{z=N} P(\ell(C(z))) \log_2 \frac{P(\ell(C(z)))}{P(\ell(S(z)))} = \xi \end{aligned}$$

(19)

Here  $P(\ell(C(z)))$  is probability distribution of the pixels in the neighbourhood of pixel  $C(z)$  and  $P(\ell(S(z)))$  is probability distribution of the pixels in the neighbourhood of pixel  $S(z)$ .

**Requirement 3**

Most spatial domain Stego Algorithms distribute the entire information in large number of pixels and as a result the changes in the pixel values are very small and unnoticeable but in this process large number of the pixels in the image change and hence the relative entropy of the stego-image and cover-image increases due to considerable change in probability distribution of pixels in the image. Security of such algorithms can be defined by Requirement 1 and Requirement 2 that is  $\epsilon$  and  $\xi$ .

But there are certain Image Stego Algorithms which concentrate the information in very few pixels. As a result the change in pixels values of these few pixels is very large and hence quiet perceptible even though the probability distribution of pixels is not much disturbed. In case of such algorithms even if  $\epsilon$  and  $\xi$  are very small the stego-image may have few grains in last few rows (grains are due to large and perceptible changes in those few pixels and changes in the bottom most pixel usually goes unnoticed due to psycho-visual weaknesses of human eye) and are susceptible to steganalysis. In any natural Image a pixel  $P$  is almost same as its neighbors. Therefore on an average  $C(z)$  will not be very different from  $\ell(C(z))$  for most values in  $z = 1$  to  $N$ . Thus  $\alpha(z)$  should meet another requirement:

Using operator  $\bullet$  the  $\alpha(z)$  should map  $C(z)$  and  $I(z)$  to  $S(z)$  in such a way that any particular pixel should not change much. Thus the difference between Weighted Mean of the Pixel Aberration of Stego-Image  $S$  from Cover-Image  $C$  (Definition 8) should be minimum possible. This difference of the weighted mean of pixel aberration  $\delta$  can be calculated by either considering the difference of the Maximum Pixel Aberration the red, green and blue values between the cover and stego image and represented as  $\dot{\epsilon}_{MAX}$  or by taking the difference of the average of the red, green and blue values of the pixel aberrations of the cover and stego image and is represented as  $\dot{\epsilon}_{MEAN}$ . Thus in general the difference between Weighted Mean of the Pixel Aberration of Stego-Image  $S$  from Cover-Image  $C$  is represented as  $\dot{\epsilon}$  and can be either  $\dot{\epsilon}_{MAX}$  and  $\dot{\epsilon}_{MEAN}$  and given as

$$\dot{\epsilon} = \dot{\epsilon}_{MAX} \text{ OR } \dot{\epsilon}_{MEAN}$$

$$\dot{\epsilon} = \dot{\epsilon}_{MAX} = MAX_{RGB}(\delta(S)) - MAX_{RGB}(\delta(C))$$

OR

$$\dot{\epsilon} = \dot{\epsilon}_{MEAN} = MEAN_{RGB}(\delta(S)) - MEAN_{RGB}(\delta(C))$$

20

The same can be alternatively represented by finding the difference between the mean pixel aberration of Cover Image  $C$  and Stego-Image  $S$  considering only those values of pixel aberrations (of  $\delta(C(z), \ell(C(z)))$  and  $\delta(S(z), \ell(S(z)))$  for  $z = 1$  to  $N$ ) in entire image which are above a certain threshold  $\pm \check{\tau}$  and given as  $\delta(C, \tau)$  and  $\delta(S, \tau)$  Thus  $\alpha(z)$  should be such

that the difference between the pixel aberrations of Stego-Image and Cover-Image at threshold  $\tau$  (in terms of standard deviation it corresponds to pixel aberration value of  $\pm \check{\tau}$ ) should be minimum possible and given as  $e(\tau)$ .

In unsmooth cover images the aberration is already very high and addition of information brings further more aberrations (in some efficient stego-algorithms it may reduce the aberrations too) so if the value of  $\tau$  is kept large then  $e(\tau)$  will be measure of differences in only those large aberrations. Whereas in smooth cover images the aberration is quite low and hence lower value of  $\tau$  is advisable. In some cases we may get a value of  $e(\tau)$  as negative which indicates that at threshold  $\tau$  the Stego Image has lesser aberration then the cover image.

Certain steganographic algorithms hide the data very efficiently and as a result only few counted pixels have aberration beyond the prescribed limit. In such cases determination of weaknesses in these algorithms using only fixed value  $e(\tau)$  goes unnoticed due to averaging effect of large number of pixels having much lower pixel aberration. Moreover  $e(\tau)$  has different value at every  $\tau$ . Thus a better estimate of  $e(\tau)$  can be  $\check{e}$  which is the mean of  $e(\tau)$  for continuously increasing value of  $\tau$  from 0 to that value of  $\tau$  which corresponds to modulus of Maximum Pixel Aberration (Definition 10) in the stego image that is for  $\tau = 0$  to  $J$ .

$$e(\tau) = \delta(S, \tau) - \delta(C, \tau)$$

$$J = \tau : \check{\tau} = \Delta(M)$$

$$\check{e} = \frac{1}{J} \int_0^J e(\tau) d\tau$$

(21)

Since calculating the value of  $\check{e} = \frac{1}{J} \int_0^J e(\tau) d\tau$  is practically very expensive in various accords of time and computation power. So more practical way to estimate of  $\check{e}$  can be based on taking means of  $e(\tau)$  at any chosen discrete values of  $\tau$  for example like  $\tau = 0, 1/8 J, 2/8 J, 3/8 J \dots J$ .

Thus as an indicator of requirement 3 either  $\bar{e} = \delta(S) - \delta(C)$  or  $\check{e} = \frac{1}{J} \int_0^J e(\tau) d\tau$  can be considered. But generally the difference of the weighted means of the pixel aberration of cover image and stego image as given as  $\bar{e}$  in (20) will be preferable although this may vary from algorithm to algorithm and situation to situation. Whatever the value we consider for obtaining this difference i.e. either  $\bar{e}$  or  $\check{e}$  has to be represented by  $\bar{e}$  in the holistic representation of the requirement 4 in the steganographic system. Thus mathematically the same can expressed as :

$$\bar{e} = \bar{e} \text{ or } \check{e} \tag{22}$$

**Requirement 4**

Another very good indicator of presence of anomaly in the pixels of the image is Range of Pixel Aberration  $\mathcal{R}(M)$  in the Image (Definition 9). Bigger value of  $\mathcal{R}(M)$  in spite of lower values of  $e(\tau)$  indicates that only very few counted pixels

have aberration much beyond the prescribed limit and hence the given image could be a potential stego-image. Thus using operator  $\bullet$  the  $\alpha(z)$  should map  $C(z)$  and  $I(z)$  to  $S(z)$  in such a way that Range of Pixel Aberration in Cover Image must not be very different from the Range of Pixel Aberration in the Stego image. Thus the difference of Range of Pixel Aberration of Cover and Stego Image should be minimum possible and given as  $\epsilon$ .

$$\epsilon = \frac{\mathcal{R}(S) - \mathcal{R}(C)}{\mathcal{R}(C)} \tag{23}$$

Thus  $\epsilon$  is the indicator of percentage change in the Range of Pixel Aberration in Cover Image after embedding the data in it.

In colored Image the  $\epsilon$  value is different for Red, Green and Blue components of the Image. But we can't take average of the three as  $\epsilon$  value represents the Range of Pixel Aberration and hence for RGB image, this  $\epsilon$  is given as

$$\epsilon = \text{MAX} (\epsilon_{\text{RED}}, \epsilon_{\text{GREEN}}, \epsilon_{\text{BLUE}}) \tag{24}$$

Also it is better if we mention the color component which has maximum  $\epsilon$  in RGB Image.

**2.4 Holistic Representation of Stego System and Universal Stego System Mathematically**

Based on these four requirements of  $\alpha$  with regards to the Strength of any Steganographic System  $\Psi$  we may define security of  $\Psi$  by four tuple  $\langle \epsilon, \xi, \bar{e}, \epsilon \rangle$  and say  $\Psi(\alpha) = \langle \epsilon, \xi, \bar{e}, \epsilon \rangle$  secure.

Thus Image based Universal stego system  $\Phi = \{ F, F^{-1}, C, S, I \}$  with any Stego System  $\Psi = \{ C, S, I, F, F^{-1} \}$  such that  $\Psi \in \Phi$  can be more elaborately defined at pixel level as

$$\Phi = \{ C, S, I, \Phi(\text{Algorithm}), \Phi(\alpha) \} \text{ and } \Psi = \{ C, S, I, \Psi(\text{Algorithm}), \Psi(\alpha) \}$$

*In other words*

$$\Phi = \{ C, S, I, \langle \bullet, \Theta \rangle, \langle \epsilon, \xi, \bar{e}, \epsilon \rangle \} \text{ and } \Psi = \{ C, S, I, \langle \bullet, \Theta \rangle, \langle \epsilon, \xi, \bar{e}, \epsilon \rangle \} \tag{25}$$

Stego-Algorithm of  $\Phi$  or  $\Phi(\text{Algorithm}) = \langle \bullet, \Theta \rangle$  and  $\Phi(F) = \bullet$  and  $\Phi(F^{-1}) = \Theta$  and Strength of  $\Phi$  given as  $\Phi(\alpha) = \langle \epsilon, \xi, \bar{e}, \epsilon \rangle$ . Since handling four different values of  $\Phi(\alpha)$  is quite difficult so four values of  $\Phi(\alpha) = \langle \epsilon, \xi, \bar{e}, \epsilon \rangle$  can be reduced in to one value represented as  $\langle \Phi(\alpha) \rangle$  by taking weighted means of their modulus.

$$\langle \Phi(\alpha) \rangle = \frac{w_1 |\epsilon| + w_2 |\xi| + w_3 |\bar{e}| + w_4 |\epsilon|}{w_1 + w_2 + w_3 + w_4} \tag{26}$$

The values of these four weights  $w_1, w_2, w_3, w_4$  depends upon the alertness and sensitivity of steganalysis algorithm with respect to the four strength parameters  $\epsilon, \xi, \bar{e}, \epsilon$  of any

steganographic algorithm. In most general cases we assume that the steganalyst is capable of exploiting any of these 4 vulnerabilities and therefore the four conditions have equal importance and hence  $w_1 = w_2 = w_3 = w_4$  and therefore the value of  $\langle \Phi(\alpha) \rangle$  becomes simple mean of  $\langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle$  and given as  $\langle \Phi(\alpha) \rangle = (\varepsilon + \xi + \bar{\varepsilon} + \epsilon)/4$ . The smaller value of  $\langle \Phi(\alpha) \rangle$  indicates that the algorithm  $\Phi$  is stronger. Thus Image based Universal stego system  $\Phi = \{ F, F^{-1}, C, S, I \}$  with any Stego System  $\Psi = \{ C, S, I, F, F^{-1} \}$  such that  $\Psi \in \Phi$  can also be defined as

$$\Phi = \{ C, S, I, \Phi(\text{Algorithm}), \langle \Phi(\alpha) \rangle \}$$

$$\text{and } \Psi = \{ C, S, I, \Psi(\text{Algorithm}), \langle \Psi(\alpha) \rangle \}$$

(27)

**2.5 Steganalysis is Always Possible**

In this section a theorem is given which proves that every stego system is susceptible to steganalysis.

**Theorem:** No Image based Stego Algorithm (Universal Stego System) is fool proof.

**Assumption:**

Let there be any fool proof Universal stego system  $\Phi = \{ C, S, I, \Phi(\text{Algorithm}), \Phi(\alpha) \}$  such that  $\Phi(\alpha) = \langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle = \langle 0, 0, 0, 0 \rangle$  and  $\Phi(\text{Algorithm}) = \{ F, F^{-1} \}$  capable of exchanging Y distinct and authentic Information  $I_1, I_2, I_3 \dots I_Y$ .

Thus mathematically this assumption can be written as:

$$\Phi = \{ C, S, I, \Phi(\text{Algorithm}), \Phi(\alpha) \}$$

$$\Phi(\alpha) = \langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle = \langle 0, 0, 0, 0 \rangle$$

$$\Phi(\text{Algorithm}) = \langle \bullet, \Theta \rangle$$

$$\text{Where } \Phi(F) = \bullet \text{ and } \Phi(F^{-1}) = \Theta$$

$$\{ I_1, I_2, I_3 \dots I_Y \} \in \mathbb{I} \text{ and } I_1 \neq I_2 \neq I_3 \neq \dots \neq I_Y \text{ and}$$

$$\text{any } I_x \in \mathbb{I} \text{ is not empty } \forall x: 1 \leq x \leq Y$$

(28)

**Proof:**

Some information  $I_k \in \mathbb{I}$  is being exchanged through above assumed Universal stego-system  $\Phi$  using cover-image  $C \in \mathbb{C}$  of size N. As any  $I_x \in \mathbb{I}$  is not empty  $\forall x: 1 \leq x \leq Y$  so information  $I_k$  will be such that  $I_k(z) \neq \{ \}$  for at least one z from 1 to N.

As  $S(z) = \alpha(z) [C(z) \bullet I_k(z)]$  and  $\Phi(\alpha) = \langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle = \langle 0, 0, 0, 0 \rangle$  so  $S(z)$  will be such that  $S(z) = C(z)$  and hence Stego Image S and Cover Image C are identical or  $S \equiv C$ .

Now a different Information  $I_m \in \mathbb{I}$  is exchanged through same Universal Stego system  $\Phi$  with same cover Image C. Again since  $S(z) = \alpha(z) [C(z) \bullet I_m(z)]$  and  $\Phi(\alpha) = \langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle$  In order to maintain uniformity in evaluation of  $\Phi_1, \Phi_2$  and  $\Phi_3$  we embed same Information I using all the three algorithms. This information I is 900 character string of abcdef....z1234 repeated 30 times. Thus  $I = \text{abcdef....z1234}$  (30 times) and  $I \in \mathbb{I}$  and  $\mathbb{I} = \{ I \}$ .

Thus mathematically the three Universal Stego Systems are summarized as:

$= \langle 0, 0, 0, 0 \rangle$  so  $S(z) = C(z)$ . Therefore again S and C are identical or  $S \equiv C$ .

Thus for any information  $I_x \in \mathbb{I}$  the Universal stego-system  $\Phi$  is such that S and C are identical and same. But as we know that  $S = F(C, I)$  and  $I = F^{-1}(S)$  so for every stego-image S there exists a unique Information I.

But in the given case the stego-image S is same for different distinct information  $I_1, I_2, I_3 \dots I_Y$ . Hence we conclude that all information are same i.e.  $I_1 = I_2 = I_3 = \dots = I_x = \dots = I_{Y-1} = I_Y$ .

But this is in contradiction with our assumption that  $\{ I_1, I_2, I_3 \dots I_Y \} \in \mathbb{I}$  and  $I_1 \neq I_2 \neq I_3 \neq \dots \neq I_Y$ .

Thus our assumption is wrong and hence  $\Phi(\alpha) = \langle \varepsilon, \xi, \bar{\varepsilon}, \epsilon \rangle \neq \langle 0, 0, 0, 0 \rangle$  and hence  $\langle \Phi(\alpha) \rangle$  is more than 0.

**3 APPLICATION OF THE MATHEMATICAL MODEL**

Based on the mathematical model developed in Section 2 three different spatial domain steganographic algorithms are evaluated for susceptibility to steganalysis. These three Algorithms are named as Algorithm I, Algorithm II and Algorithm III and represented mathematically as Universal Stego Systems  $\Phi_1, \Phi_2$  and  $\Phi_3$  respectively. These three steganographic algorithms were also used in [1] and are referred in Section 5 of [1] as *Algorithm designed in section 4, QuickStego Software* and *Eureka Steganographer* respectively. Thus  $\Phi_1(\text{Algorithm})$  is Algorithm I,  $\Phi_2(\text{Algorithm})$  is Algorithm II and  $\Phi_3(\text{Algorithm})$  is Algorithm III. The features of these three algorithms are summarized in Table 1.

For the sake of uniformity (which is required for Evaluation) we use same set of two different cover images for evaluation of  $\Phi_1, \Phi_2$  and  $\Phi_3$ . One of them is smooth (has low Pixel Aberration) and other is relatively unsmooth and has high Pixel Aberration and hence named as Smooth and Unsmooth and mathematically represented as *smooth* and *unsmooth* respectively.. Thus set of Cover Images  $\mathbb{C} = \{ \text{smooth}, \text{unsmooth} \}$  and  $C \in \Phi_1, C \in \Phi_2$  and  $C \in \Phi_3$  and  $\delta(\text{smooth}) < \delta(\text{unsmooth})$ . The two cover images smooth and unsmooth are shown in Figure 1. Based on various parameters of Image mentioned in Section 2.2 the properties of these two images are summarized in Table 2. These parameters are calculated using MATLAB© Image Processing Tool Box.

$$\begin{aligned}
 \Phi_1 &= \{ C, S, I, \Phi_1(\text{Algorithm}), \Phi_1(\alpha) \} \\
 \Phi_2 &= \{ C, S, I, \Phi_2(\text{Algorithm}), \Phi_2(\alpha) \} \\
 \Phi_3 &= \{ C, S, I, \Phi_3(\text{Algorithm}), \Phi_3(\alpha) \} \\
 C &= \{ \text{smooth}, \text{unsmooth} \} \\
 C &\in \Phi_1, C \in \Phi_2 \text{ and } C \in \Phi_3. \\
 \{I\} &= I \\
 I &= \text{abcdef...z1234 (30 times)} \\
 I &\in \Phi_1, I \in \Phi_2 \text{ and } I \in \Phi_3
 \end{aligned}
 \tag{29}$$

Using 2 cover Images  $C = \{ \text{smooth}, \text{unsmooth} \}$  and three Universal Stego Systems  $\Phi_1, \Phi_2$  and  $\Phi_3$  we obtain Six Stego-Systems given as  $\Psi_{1S}, \Psi_{1U}, \Psi_{2S}, \Psi_{2U}, \Psi_{3S}$  and  $\Psi_{3U}$ . These six stego systems are mathematically given as:

$$\begin{aligned}
 \text{Stego-System } \Psi_{1S}: \Psi_{1S} \in \Phi_1 \text{ and} \\
 \Psi_{1S} &= \{ \text{smooth}, S_1^S, I, \Psi_{1S}(\text{Algorithm}), \Psi_{1S}(\alpha) \} \\
 \text{Stego-System } \Psi_{1U}: \Psi_{1U} \in \Phi_1 \text{ and} \\
 \Psi_{1U} &= \{ \text{unsmooth}, S_1^U, I, \Psi_{1U}(\text{Algorithm}), \Psi_{1U}(\alpha) \} \\
 \text{Stego-System } \Psi_{2S}: \Psi_{2S} \in \Phi_2 \text{ and} \\
 \Psi_{2S} &= \{ \text{smooth}, S_2^S, I, \Psi_{2S}(\text{Algorithm}), \Psi_{2S}(\alpha) \} \\
 \text{Stego-System } \Psi_{2U}: \Psi_{2U} \in \Phi_2 \text{ and} \\
 \Psi_{2U} &= \{ \text{unsmooth}, S_2^U, I, \Psi_{2U}(\text{Algorithm}), \Psi_{2U}(\alpha) \} \\
 \text{Stego-System } \Psi_{3S}: \Psi_{3S} \in \Phi_3 \text{ and} \\
 \Psi_{3S} &= \{ \text{smooth}, S_3^S, I, \Psi_{3S}(\text{Algorithm}), \Psi_{3S}(\alpha) \} \\
 \text{Stego-System } \Psi_{3U}: \Psi_{3U} \in \Phi_3 \text{ and} \\
 \Psi_{3U} &= \{ \text{unsmooth}, S_3^U, I, \Psi_{3U}(\text{Algorithm}), \Psi_{3U}(\alpha) \}
 \end{aligned}
 \tag{30A}$$

Here  $S_1^S, S_2^S, S_3^S$  are the three stego-images generated by using image *smooth* as Cover-image through 3 stego algorithms  $\Phi_1, \Phi_2$  and  $\Phi_3$  respectively. And  $S_1^U, S_2^U$  and  $S_3^U$  are three stego-images generated by using image *unsmooth* as Cover-image through 3 stego-algorithms  $\Phi_1, \Phi_2$  and  $\Phi_3$  respectively.

Security of  $\Phi_1, \Phi_2$  and  $\Phi_3$  ie  $\Phi_1(\alpha), \Phi_2(\alpha)$  and  $\Phi_3(\alpha)$  is to be determined. It will be obtained by calculating the security ( $\epsilon, \xi, \bar{\epsilon}$  and  $\epsilon$  values) of all the six stego systems i.e.  $\Psi_{1S}(\alpha), \Psi_{1U}(\alpha), \Psi_{2S}(\alpha), \Psi_{2U}(\alpha), \Psi_{3S}(\alpha)$  and  $\Psi_{3U}(\alpha)$  and applying (3) on them. In all of these cases the value of  $\bar{\epsilon}$  is determined from the value of  $\bar{\epsilon}$  and not  $\bar{\epsilon}$ . Although final result with even  $\bar{\epsilon} = \bar{\epsilon}$  would had been the same but little more decisive and clear.

**3.1 Results**

The values of  $\Psi_{1S}(\alpha), \Psi_{1U}(\alpha), \Psi_{2S}(\alpha), \Psi_{2U}(\alpha), \Psi_{3S}(\alpha)$  and  $\Psi_{3U}(\alpha)$  are calculated using programs in MATLAB© Image Processing Tool Box.

First step for calculating the values of  $\Psi_{1S}(\alpha), \Psi_{1U}(\alpha), \Psi_{2S}(\alpha), \Psi_{2U}(\alpha), \Psi_{3S}(\alpha)$  and  $\Psi_{3U}(\alpha)$  is to determine the corresponding value of  $\bar{\epsilon}$ . This value of  $\bar{\epsilon}$  is determined by taking means of  $e(\tau)$  for  $\tau = 0, 2, 4.5, 6$  and  $7.9$ . All these values of  $e(\tau)$  and  $\bar{\epsilon}$  are given in Table 3a (for Smooth Image) and Table 3b (for Unsmooth Image). These values of  $e(\tau)$  for different  $\tau$  and their average  $\bar{\epsilon}$  are the measure of the difference between the pixel aberrations in the Stego-Image and the Cover-Image. Hence in order to better understand and appreciate the values of  $e(\tau)$  and  $\bar{\epsilon}$  it becomes necessary to plot the value of pixel aberration of each and every pixel (given as  $\delta ( M(z), \ell(M(z)))$  in Definiton 7 of Section 2.2) in the Cover Image and corresponding three Stego-Images (generated by the three stego-algorithms  $\Phi_1, \Phi_2$  and  $\Phi_3$  operating on cover-image). As we have two different cover-images given by  $C = \{ \text{smooth}, \text{unsmooth} \}$  so in Figure 2.a the pixel aberration for smooth cover-image and associated stego images are plotted whereas in Figure 2.b the pixel aberration of unsmooth cover-image and the associated stego-images are plotted. In otherwords in Figure 2.a the pixel aberration  $\delta ( M(z), \ell(M(z)))$  is plotted for  $M = \text{smooth}, S_1^S, S_2^S$  and  $S_3^S$  whereas in Figure 2.b the pixel aberration is plotted for  $M = \text{unsmooth}, S_1^U, S_2^U$  and  $S_3^U$ . The various symbols used in the plot have their usual meaning. Based on the mean of the values of  $\epsilon, \xi$  and  $\epsilon$  and  $\bar{\epsilon}$  (as calculated in Table 3a and Table 3b) for all six stego-systems  $\Psi_{1S}, \Psi_{1U}, \Psi_{2S}, \Psi_{2U}, \Psi_{3S}$  and  $\Psi_{3U}$  their overall strengths given as  $\langle \Psi_{1S}(\alpha) \rangle, \langle \Psi_{1U}(\alpha) \rangle, \langle \Psi_{2S}(\alpha) \rangle, \langle \Psi_{2U}(\alpha) \rangle, \langle \Psi_{3S}(\alpha) \rangle$  and  $\langle \Psi_{3U}(\alpha) \rangle$  are calculated and shown in Table 4.

In order to better understand the values of  $\epsilon, \xi$  the plots of relative entropy of the neighborhood (given as  $H(P(\ell(C(z))))|P(\ell(S(z)))$  in Section 2.3.1, Requirement 2) of every pixel for all the three stego-algorithms is plotted in Fig 3.a and Fig 3.b. In Fig 3.a the cover image  $C = \text{smooth}$  and Stego Image  $S = S_1^S, S_2^S$  and  $S_3^S$  where as in Fig 3.b the cover image used is  $C = \text{unsmooth}$  and stego image  $S = S_1^U, S_2^U$  and  $S_3^U$ . By applying (3) on these values we can conclude that:

$$\begin{aligned}
 \langle \Phi_1(\alpha) \rangle &= \text{MAX} ( \langle \Psi_{1S}(\alpha) \rangle, \langle \Psi_{1U}(\alpha) \rangle ) \\
 \langle \Phi_2(\alpha) \rangle &= \text{MAX} ( \langle \Psi_{2S}(\alpha) \rangle, \langle \Psi_{2U}(\alpha) \rangle ) \\
 \langle \Phi_3(\alpha) \rangle &= \text{MAX} ( \langle \Psi_{3S}(\alpha) \rangle, \langle \Psi_{3U}(\alpha) \rangle )
 \end{aligned}
 \tag{31}$$

TABLE 1

THREE DIFFERENT STEGANOGRAPHIC ALGORITHMS USED FOR EVALUATION OF SUSCEPTIBILITY TO STEGANALYSIS

Feature	Algorithm I or $\Phi_1(\text{Algorithm})$	Algorithm II or $\Phi_2(\text{Algorithm})$	Algorithm III or $\Phi_3(\text{Algorithm})$
Number of pixels changed if N characters are hidden in the cover image	N+1	0.3353N + 1.8096	1.534N+39.5963
Range of change in pixel values	-3 to +3	-1 to +1	Variable but ranges from -253 to +246
Data Insertion Technique	2 Bit LSB Insertion	1 Bit LSB Insertion	around 6 to 7 bits are used for data Insertion

Distribution of data in the pixel	Continuously inserts data Row by Row in every pixel right from the first row onwards. As a result the data is continuously distributed in every pixel.	Enters data in such a way that cover image and stego image remain more or less the same by pixel values having equal number of changes in +1 and -1 values so that net change in pixel value may remain close to zero.	Makes very large change in the bottom most pixels (changes in the bottom most pixel usually goes unnoticed due to psycho-visual weaknesses of human eye)					
Concentration of Information in Pixel	low	Very low	Very high					
Degree of Difference between the Cover Image and Stego Image (It is expressed in the scale of 1 and measured using Mean absolute Difference in the Intensity Levels of Cover and Stego Image)	0.1186	0.0671	1.00000					
Degree of Changes in neighboring pixels of the pixel changed	Always Very high because it inserts data row by row.	High to Low depending on size of Cover Image	Low					
Source of Algorithm	Designed in section 4 of [1]	<a href="http://quickcrypto.com/free-steganography-software.html">http://quickcrypto.com/free-steganography-software.html</a>	<a href="http://www.brothersoft.com/ureka-steganographer-v2-266233.html">http://www.brothersoft.com/ureka-steganographer-v2-266233.html</a>

	Red	0.0470	2.6542	4.8776	5.4672	6.0756			
	Green	0.0539	3.2605	5.4122	6.8352	7.7026			
	Blue	0.0439	2.6896	3.4502	4.1124	4.0975			

TABLE 4  
VALUES OF  $\Psi_{1S}(\alpha)$ ,  $\Psi_{1U}(\alpha)$ ,  $\Psi_{2S}(\alpha)$ ,  $\Psi_{2U}(\alpha)$ ,  $\Psi_{3S}(\alpha)$  AND  $\Psi_{3U}(\alpha)$

<i>smooth</i> image					
	$\epsilon$	$\xi$	$\bar{e}$	€ & Color	Overall Strength
$\Psi_{1S}(\alpha)$ (Algo)	0.0294	2.2342	0.225255	0.4395 (R)	$\langle \Psi_{1S}(\alpha) \rangle = 0.732089$
$\Psi_{2S}(\alpha)$ , (QS)	0.0663	1.3917	0.792884	1.0720 (R)	$\langle \Psi_{2S}(\alpha) \rangle = 0.830721$
$\Psi_{3S}(\alpha)$ Eureka)	0.0292	0.5931	7.794545	11.6579 (B)	$\langle \Psi_{3S}(\alpha) \rangle = 5.018686$
<i>Unsmooth</i> image					
	$\epsilon$	$\xi$	$\bar{e}$	€ & Color	Overall Security
$\Psi_{1U}(\alpha)$	0.0425	1.8252	0.108875	-0.1221(R)	$\langle \Psi_{1U}(\alpha) \rangle = 0.524669$
$\Psi_{2U}(\alpha)$	0.0313	3.8054	-0.004	-0.0120(B)	$\langle \Psi_{2U}(\alpha) \rangle = 0.963175$
$\Psi_{3U}(\alpha)$	0.0086	0.9851	3.268105	3.4274 (G)	$\langle \Psi_{3U}(\alpha) \rangle = 2.560202$

So  
 $\langle \Phi_1(\alpha) \rangle = \text{MAX}(0.732089, 0.524669) = 0.732089$   
 $\langle \Phi_2(\alpha) \rangle = \text{MAX}(0.830721, 0.963175) = 0.963175$

$\langle \Phi_3(\alpha) \rangle = \text{MAX}(5.018686, 2.560202) = 5.018686$   
 So Algorithm 1 is most secure among all the three stego algorithms and Algorithm 3 is least secure.

**3.1.1 Observations:**

In Table 4 we notice that Algorithm 3 is the least secure among all three and Algorithm 1 is the most secure. Further it is interesting to note that Algorithm 2 performs better when the image is smooth where as Algorithm 1 and Algorithm 3 performs better when the image is unsmooth. In Table 3.a and Table 3.b certain values of  $e(\tau)$  are negative for certain specific  $\tau$  ( $e(\tau)$  is especially negative at  $\tau=2$  for  $\Psi_{1s}$  and  $\Psi_{2s}$  in Table 3.a). This indicates that when the pixel aberrations of  $\tau \geq 2$  (pixels which are more than 95% deviated from the neighborhood) are considered then the cover image has more aberrations than the stego-image which indicates that the stego-algorithm reduce the pixel aberration in the stego-image for certain pixels within the values of  $\tau=2$ . In Figure 2.a we notice that although Algorithm 2 has minimum pixel aberration among all the three but due to very high pixel aberration produced in one particular pixel (pixel aberration of more than 10 at pixel value  $S_2^s(1000)$  ie at 1000<sup>th</sup> pixel) of stego image  $S_2^s$  it becomes quite susceptible to Steganalysis. Algorithm 1 performs better because it produces stego image by inserting data row by row in every pixel of cover image thus entire neighborhood of the pixel changes rendering steganalysis based on analysis of pixel aberration ineffective. Algorithm 3 has the highest pixel aberrations among all the three algorithms (clearly seen in Table 2.a and 2.b and Figure 2.a and 2.b) because it

concentrates the entire information in very few pixels of bottom most row of the image. Since very few pixels are changed by Algorithm 3 so it has the minimum Relative Entropy among all the three and this is clearly conspicuous in Figure 3.a and 3.b. The graphs in Fig 3.a and 3.b are shifted Right for Algorithm 3 because it changes only the last few pixels of the cover image. From Figure 3.a and 3.b we can also conclude that Relative Entropy is highest in Algorithm 2. This is because Algorithm 2 distributes the entire information in large number of pixels as a result the probability distribution of large number of pixels changes in the stego-image (almost every pixel shows some value for relative entropy). In Algorithm 1 the graph of relative entropy (Figure 3.a and 3.b) has shifted Left and this indicates that it changes only first few pixels (exactly 900 pixels, one pixel for each character of I).

**4. CONCLUSION**

Based on the mathematical model designed in Section 2 three different stego-algorithms were represented mathematically. Their relative strengths and weaknesses could be easily represented using the mathematical parameters and requirements defined in Section 2. Based on these mathematical parameters we can also identify any innocent looking image to be a stego image if those parameters are significantly different. Above all this model can be used for further research in Image Steganography and for representing any Image based steganographic algorithm mathematically.
