

Modeling The Influential Factors Of 8th Grades Student's Mathematics Achievement In Malaysia By Using Structural Equation Modeling (SEM)

Ahmad Nazim, Sabri Ahmad

Abstract— This research study the application of Structural Equation Modeling (SEM) method in order to obtain the best fit model for a more efficient and accurate inter-relationship among variables findings and interpretation. For the purpose of this study, secondary data of Trends in International Mathematics and Science Study (TIMSS) was used. The questionnaire were distributed by using two stage stratified cluster sampling technique to 5733 eighth grades students in Malaysia. A Confirmatory Factor Analysis (CFA), Discriminant Validity and Path Analysis had been conducted to obtain the best fit model of SEM. At the end of the study, a best fit model will be obtained for a better accuracy and precision estimation in further analysis.

Index Terms— Structural Equation Modeling, SEM, Confirmatory Factor Analysis, CFA, Mediation, Path Analysis, Discriminant Analysis

1 INTRODUCTION

Structural Equation Modeling or also known as SEM has gained popularity among researchers, academicians and students nowadays [15]. It is due to its flexibility and generality besides can generate an accurate and precise estimation in making prediction. SEM analysis goes through the steps of model specification, data collection, model estimation, model evaluation and also model modification[15].

SEM is a unique method because the researcher can modify the structural model in order to increase the model fitness. A secondary data obtained from Trends in Mathematics and Science Study (TIMSS) will be used to apply SEM method in order to obtain a best fit model for further analysis.

2 MATERIALS AND METHOD

2.1 Sample Of The Study

The population of the study is defined as the eighth grades (form two) students in Malaysia. Our target population is eighth grades students in Malaysia. A value of 5733 respondents was randomly chosen from 180 randomly chosen schools in Malaysia. In this case study, eighth grades student's attitude towards Mathematics acts as mediating variable and achievement in Mathematics examination acts as dependent variable for this study.

Data were obtained from the Trends in International Mathematics and Science Study (TIMSS) international database. Respondents were normally selected through a two stage stratified cluster sampling technique in which consist of cluster sampling for the first stage, school sampling for the second stage and class sampling for the third stage. The questionnaire consists of four independent variables which are; school environment, teacher's characteristics, student's self-confidence in Mathematics and student's motivation in Mathematics. It also includes student's attitude in Mathematics which acts as mediating variable and student's Mathematics achievement as the dependent variable. The data mining software SPSS PASW

version 18.0 and SPSS AMOS were used for the purpose of building model. Several analysis used in this study are Confirmatory Factor Analysis (CFA), Discriminant Validity, Path Analysis, Structural Equation Modeling (SEM) and Chi Square test.

2.2 Confirmatory Factor Analysis (CFA)

CFA is a special form of factor analysis, most commonly used in social research [1]. It is different compared to Exploratory Factor Analysis (EFA) since it is used to test whether measures of a construct consistent with a researcher's understanding of the nature of that construct (or factor). As such, the objective of CFA is to test whether the data fit a hypothesized measurement model. Model fit measures could then be obtained to assess how well the proposed model captured the covariance between all the items or measures in the model [15]. All redundant items exist in a latent construct will be either removed or constrained [1]. Model fitness estimations are as follows:

TABLE 1
FITNESS INDEXES ESTIMATION

Name of Category	Name of Index	Level of Acceptance	Literature
Factor Loading	Standardized Regression Weight	Weight > 0.5	Heir et al (2006)
Absolute Fit	Chisq RMSEA GFI	P > 0.05 RMSEA < 0.08 GFI > 0.9	Wheaton et al. (1977) Browne and Cudeck (1993) Joreskog and Sorbom (1984)
Incremental Fit	AGFI CFI TLI NFI	AGFI > 0.9 CFI > 0.9 TLI > 0.9 NFI > 0.9	Tanaka and Huba (1985) Bentler (1990) Bentler and Bonett (1980) Bollen (1989)
Parsimonious Fit	Chisq/df	Chisq/df < 5.0	Marsh and Hocevar (1985)

2.3 Discriminant Validity

Discriminant validity is the degree to which scores on a test do not correlate with scores from other tests that are not designed to assess the same construct. Correlation coefficients between measures of a construct and measures of conceptually different constructs are usually given as evidence of discriminant validity. If the correlation coefficient is high (>0.85), then the discriminant validity is considered as weak, depending on the theoretical relationship and the magnitude of the coefficient. On the other hand, if the correlations are low to moderate, this demonstrates that the measure has discriminant validity.

$$\text{Correlation coefficient} = \frac{r_{xy}}{\sqrt{r_{xx} r_{yy}}}$$

where:

r_{xy} = correlation between x and y

r_{xx} = reliability of x

r_{yy} = reliability of y

2.4 Path Analysis

Path Analysis can test the significance of mediator variable in linking independent variables to dependent variable or simply called as mediation test. It can determine the existence of direct and indirect effect of independent variable towards dependent variable. Usually in SPSS/ANOVA, the conventional regression needs to be analyzed separately in order to determine the mediating effect. However in AMOS, the regression equations can be run simultaneously in one diagram. There are three types of mediation which are:

- 1) Complete mediation: Occur when the independent variable links towards the dependent variable only through mediator variable and there is no direct effect of independent variable towards dependent variable.
- 2) Partial mediation: Occur when independent variable links towards the dependent variable through mediator variable and there is also a direct effect of independent variable towards dependent variable.
- 3) No mediation: Occur when independent variable does not link to the dependent variable through mediator variable but has a direct effect towards dependent variable.

Fig. 1 shows the example of a mediation in a construct model

2.5 Structural Equation Modeling (SEM)

SEM is a second generation statistical analysis techniques developed for analyzing the inter-relationships among multiple variables in a model. The relationships among variables could be expressed in a series of single and multiple regression equations. SEM technique employs the combination of quantitative and the correlational or causal assumptions into the model [15]. SEM can indirectly estimates the items under latent construct individually. Latent construct is the variable which can't be measure directly since it is only a hypothetical concept of a research. Latent construct is also known as unobserved variables, it is measured using a set of items in a questionnaire. The use of SEM is also able to model the relationship among these constructs and analyze them simultaneously.

3 RESULT AND FINDING

TABLE 2
CONFIRMATORY FACTOR ANALYSIS SUMMARY TABLE

Construct	Item	Factor Loading	Cronbach Alpha	CR	AVE
School	sch1	.679	0.712	0.714	0.6740
	sch2	.654			
	sch3	.689			
Teacher	tea1	.570	0.792	0.795	0.6995
	tea3	.704			
	tea4	.802			
	tea5	.722			
Confidence	sc1	.727	0.710	0.770	0.726
	sc4	.711			
	sc6	.740			
Motivation	mot1	.491	0.767	0.7751	0.633
	mot3	.823			
	mot4	.762			
	mot5	.566			
	mot6	.523			
Attitude	att1	.852	0.826	0.8409	0.7463
	att3	.529			
	att4	.696			
	att5	.908			
Achievement	ach01	.861	0.990	0.9402	0.8925
	ach02	.936			
	ach03	.900			
	ach04	.873			

Table 2 shows the Factor Loading, Cronbach Alpha, Critical Ratio (CR) and Average Variance Extracted (AVE) values of each latent constructs. According to Zainudin (2012), the factor loading for a newly developed scale must be higher or equal to 0.5. In this study, items with factor loading value of lower than 0.5 were dropped one at a time (starts with the lowest value) from its' constructs until the unidimensionality, parsimonious, indices of a pair of items are greater than 15, the items need to be set as 'free parameter estimate' or constrained to avoid insignificant of model fitness later on. In this study, items (ach01 and ach04, mot1 and mot5, mot1 and mot6, mot3 and mot5) have MI value of greater than 15 and were constrained Besides that, items att2, sc3 and mot2 were removed because have an extreme correlation with

items att3, sc5 and mot1 with MI values of 753.8, 566.156 and 252.866 respectively.

As for measurement values, all constructs have achieved the minimum estimation required which are 0.70 for Cronbach Alpha, 0.60 for CR and 0.50 for AVE. Therefore, it can be concluded that Convergent Validity ($AVE \geq 0.5$), Internal Reliability (Cronbach Alpha ≥ 0.6) and Construct Reliability (CR ≥ 0.60) of all constructs had been achieved.

TABLE 3
THE LATENT CONSTRUCTS FITNESS INDEXES

Construct	Parsimonious Fit	Incremental Fit			Absolute Fit	
	Chisq/Df	TLI	CFI	AGFI	GFI	RMSEA
School	4.273	.993	.998	.996	.999	.025
Attitude	3.966	.993	.998	.989	.998	.046
Confidence	3.277	.997	.999	.997	.999	.021
Motivation	2.956	.997	.999	.997	1.00	.020
Teacher	4.904	.995	.998	.994	.999	.031
Achievement	3.156	.988	.998	.962	.996	.046

Table 3 shows the fitness indices of all latent constructs in the model. All constructs have a ChiSq/df value of less than 5.0, therefore the Parsimonious fit had been achieved. Constructs also have TLI, CFI, AGFI and GFI values of higher than 0.9 and RMSEA value of less than 0.05. Therefore, Incremental and Absolute fitness also had been achieved. It can be concluded that all fitness indexes required in a model had been achieved.

Figure 2 shows the strength of correlation between all constructs in the model. All constructs have correlations of less than 0.85. It can be concluded that discriminant validity had been achieved and no construct need to be dropped from the model.

TABLE 5
UNSTANDARDIZED REGRESSION WEIGHT OF MODEL

			Estimate	SE
attitude	<--	teacher	.333	.021
attitude	<--	motivation	.301	.031
attitude	<--	confidence	.542	.022
attitude	<--	school	-.031	.022
achievement	<--	school	-.181	.019
achievement	<--	teacher	-.176	.018
achievement	<--	confidence	.167	.020
achievement	<--	motivation	.098	.025
achievement	<--	attitude	.183	.019

Table 5 above shows the value of regression weight for the independent latent constructs toward attitude (mediating) and achievement (dependent) variables. All independent latent constructs have significant effect towards both attitude and achievement variables thus have partial mediation role in linking to achievement except for school variable which is not significantly link to attitude. Therefore, school variable has no mediation in linking with achievement.

Fig.3 shows the final model obtained when all fitness indexes have achieved.

TABLE 6
MODEL FITNESS

Model	CMIN	DF	CMIN/DF	RMSEA
Default model	944.218	257	3.674	0.044

Table 6 indicates that the model has achieved a good fit model since the ChiSquare/df value is less than 5.0 and RMSEA value is less than 0.08

4 CONCLUSION

From the analysis that had been conducted for SEM method, in Confirmatory Factor Analysis (CFA) and pooled Confirmatory Factor Analysis (CFA) processes, redundant items had been either removed or constrained in the model to achieve unidimen-

sionality. At the end of the processes, convergent validity, internal reliability and constructs reliability of all constructs had been achieved. In addition, discriminant validity of the model was achieved since the correlations between constructs in the model are below 0.85. In path analysis, the type of mediations exist between constructs were determined and re-specified in order to obtain the actual influential structural model. At the end of the modelling process, the Chi-Square/df value was obtained and it shows a value of 3.674 which conclude that the model is now in its best structure for further analysis for a more efficient and accurate inter-relationship among variables findings and interpretation.

IJSER style is to not citations in individual brackets, followed by a comma, e.g. "[1], [5]" (as opposed to the more common "[1, 5]" form.) Citation ranges should be formatted as follows: [1], [2], [3], [4] (as opposed to [1]-[4], which is not IJSER style). When citing a section in a book, please give the relevant page numbers [2]. In sentences, refer simply to the reference number, as in [3]. Do not use "Ref. [3]" or "reference [3]" At the beginning of a sentence use the author names instead of "Reference [3]," e.g., "Smith and Smith [3] show" Please note that references will be formatted by IJSER production staff in the same order provided by the author.
